Lattice QCD has, in recent years, seen important progress on several fronts: there exist lattice regularizations preserving exact chiral symmetry in the limit of vanishing quark masses, while algorithmic and technological advances have put lattices fine enough to simulate physical light-quark masses within reach. As a result, non-perturbative results in the physics of light quarks with a precision of a few percent or better become achievable with current or upcoming simulations [1]. These include the masses of the light quarks, as well as hadronic matrix elements such as $B_K$, figuring prominently in the unitarity triangle analysis. At such high precision, choices of renormalization scheme and associated perturbative higher-order effects become an important source of uncertainty. Two standard methods have emerged: the use of momentum-space subtraction schemes that can be non-perturbatively implemented on a lattice [2] and the Schrödinger functional method [3], where so-called renormalization-group-invariant (RGI) masses and matrix elements are obtained via a direct implementation of the renormalization group on the lattice. Within the former approach, parameters need a further conversion to purely renormalization-group-invariant (RGI) masses and matrix elements such as $\mu$-dependence is explicitly restored through a suitable non-perturbative renormalized scheme, or its variant $\overline{\text{MS}}$ scheme, as “measured” on the lattice. We find much smaller perturbative corrections than in the RI/MOM case, extending one-loop findings in [7] and implying percent-level uncertainties on the $\overline{\text{MS}}$ masses.

I. RI'/MOM, RI/SMOM, AND RI'/SMOM$_\mu$

In the RI'/MOM renormalization scheme for the quark field and mass, two conditions, [2]

$$\lim_{m_\pi \to 0} \frac{1}{12\mu^2} \text{tr}[S_R^{-1}(p)\hat{\rho}]_{\mu^2} = -1,$$

$$\lim_{m_\pi \to 0} \frac{1}{12m_R^2} \text{tr}[S_R^{-1}(p)]_{\mu^2} = 1,$$

are imposed on the inverse quark propagator $S_R^{-1}$, where $\overline{\text{MS}}$ scheme is defined through (our notation closely follows [7])

$$- i S_B(p) = \int d^4x e^{ipx} \langle T(\bar{\psi}_B(x)\psi_B(0)) \rangle.$$
and the traces are over color and Dirac indices. (1) and (2) determine the renormalization constants $Z_q$ and $Z_m$ relating bare and renormalized field and mass, $\psi_R = Z_q^{1/2} \psi_R$ and $m_R = Z_m m_B$. Both renormalization constants depend implicitly on the regulator (lattice, dimensional regularization, etc.) and on the gauge coupling and the gauge parameter. A virtue of the RI'/MOM scheme is that it can be implemented nonperturbatively on the lattice as well as in dimensionally regularized continuum perturbation theory. The RI'/MOM field and mass can then be converted perturbatively to the $\overline{\text{MS}}$ scheme via $\psi_R = (Z_q^{RI'/MOM}/Z_q^{RI'/MOM})^{1/2} \psi_R^{RI'/MOM}$ and $m_R = Z_m^{RI'/MOM}/Z_m^{RI'/MOM}$, where all renormalization constants have to be computed with the same (but otherwise arbitrary) regulator. Both conversion factors are known to three-loop accuracy [6,8]. However, the perturbation series does not converge well, and this constitutes a drawback of using the RI'/MOM scheme for extracting light-quark masses from lattice simulations. Another issue is the influence of nonperturbative long-distance physics. This is most clearly seen by considering (nonsinglet) axial-current Ward identities such as

$$q_{\mu} \Lambda_{A,B}^\mu(p, p') = S_B(p')^{-1}(p)^\gamma_5 + \gamma_5 S_B(p)^{-1}(p) + i(m_{a,B} + m_{s,B}) \Lambda_{A,B}(p, p'),$$

where $q = p - p'$, and the bare vertex functions $\Lambda_{A,B}^\mu$ for the axial current and $\Lambda_{A,B}$ for the pseudoscalar density are defined through

$$S_B(p') \Lambda_{A,B}^\mu(p, p') S_B(p) = \int d^4 x d^4 y e^{i p' x} e^{-i p y} \langle T \left( [i \bar{u}_B \gamma^\mu \gamma_5 s_B](0) u_B(x) \bar{s}_B(y) \right) \rangle,$$

and

$$S_B(p') \Lambda_{A,B}(p, p') S_B(p) = \int d^4 x d^4 y e^{i p' x} e^{-i p y} \langle T \left( [i \bar{u}_B \gamma_5 s_B](0) u_B(x) \bar{s}_B(y) \right) \rangle.$$

(4) holds for a regulator which respects chiral symmetry (in the limit $m_B \to 0$). This is the case for certain lattice regularizations and for dimensional regularization with anticommuting $\gamma_5$. The use of anticommuting $\gamma_5$ is unproblematic here, as (4) and the formulae below do not involve closed traces containing odd powers of $\gamma_5$. To preserve (4) under renormalization, the axial current must not be renormalized, and the renormalization constant $Z_p$ of the pseudoscalar density must satisfy $Z_p = Z_p^{-1}$, where $Z_p$ can be fixed by imposing the condition

$$\Lambda(p^2, p'^2, q^2) = Z_p^{-1} \Lambda(p^2, p'^2, q^2) \Rightarrow Z_p^{-1} \Lambda(p, p') \gamma_5 \frac{1}{4} = 12$$

at a suitable subtraction point. The choice $p^2 = p'^2 = -\mu^2$, $q^2 = 0$ corresponds to (2). But at $q^2 = 0$, $\Lambda(p, p')$ receives contributions from the kaon (pseudo-Goldstone) pole, which diverge in the chiral limit $m_B \to 0$ [2], and is sensitive to condensate effects suppressed only by $(\Lambda_{\text{QCD}}/\mu)^2$ [5]. In [7], a modified renormalization scheme, termed RI/SMOM, was proposed, which is less sensitive to these effects. In that scheme, (7) is imposed at the symmetric point $p^2 = p'^2 = q^2 \equiv -\mu^2$. Following [7], we will consider a more general kinematic configuration $p^2 = p'^2 = -\mu^2$, $q^2 = -\omega \mu^2$ below, and define conversion factors

$$C_{q}^{RI/SMOM} = C_{q}^{RI'/MOM} = \frac{Z_m^{\overline{\text{MS}}}}{Z_m^{RI'/MOM}} = \frac{12 \mu^2 Z_m^{\overline{\text{MS}}}}{\sigma_B(-\mu^2)}$$

and

$$C_{\omega}^{RI/SMOM} = \frac{Z_m^{\overline{\text{MS}}}}{Z_m^{RI/SMOM}} = \frac{Z_m^{\overline{\text{MS}}}}{\sigma_B(-\mu^2)} \mu^2 \lambda_B(-\mu^2, -\mu^2, -\omega \mu^2)$$

where $\sigma_B(p^2) \equiv \text{tr} [S_B^{-1}(p) \hat{\phi}]$. The rightmost expression in (9) has a straightforward perturbation expansion. Moreover, in [7] a variant scheme RI/SMOM$_\gamma$, was introduced where the field renormalization condition (1) is replaced by the requirement

$$\Lambda(p^2, p'^2, q^2) = Z_q^{-1} \Lambda(p^2, p'^2, q^2) \frac{1}{4} = 48,$$

which implies conversion factors

$$C_{q}^{\text{RI/SMOM}_\gamma} = \frac{48 Z_m^{\overline{\text{MS}}}}{\lambda_B(-\mu^2, -\mu^2, -\omega \mu^2)},$$

and

$$C_{\omega}^{\text{RI/SMOM}_\gamma} = \frac{48 Z_m^{\overline{\text{MS}}}}{\lambda_B(-\mu^2, -\mu^2, -\omega \mu^2)} \mu^2 \lambda_B(-\mu^2, -\mu^2, -\omega \mu^2).$$

The schemes for field and mass are converted as

$$\psi^{\overline{\text{MS}}} = (C_q^{X})^{1/2} \psi^X, \quad m^{\overline{\text{MS}}} = C_m^{X} m^X,$$

where $X = \text{RI}/\text{SMOM}$ or RI/SMOM$_\gamma$. We note that $C_q^{X}$ and $C_m^{X}$ depend on $\ln \mu^2 / \nu^2 = \ln \nu$, where $\nu$ is the dimensional renormalization scale, and implicitly on $\nu$ through the scale dependence of $\alpha_s$ and the gauge parameter $\xi$. Setting $\mu \equiv \nu$ allows relating the anomalous dimensions in the RI/SMOM schemes to those in the $\overline{\text{MS}}$ scheme [9–12] according to

$$\gamma_\nu^X = \gamma_\nu^{\overline{\text{MS}}} + \frac{\beta(\alpha_s)}{4} \frac{\partial}{\partial (\alpha_s)} \frac{\partial}{\partial \xi} \ln C_m^{X} |_{\nu = 1},$$

and

$$\gamma_q^X = \gamma_q^{\overline{\text{MS}}} + \frac{\beta(\alpha_s)}{4} \frac{\partial}{\partial (\alpha_s)} \frac{\partial}{\partial \xi} \ln C_q^{X} |_{\nu = 1}.$$
\[ y_m^Y = \mu^2 d \frac{d}{d\mu^2} m_Y, \quad y_q^Y = 2\mu^2 d \frac{d}{d\mu^2} \psi_Y, \] (16)

\[ \beta(\alpha_s) = \mu^2 d \frac{d}{d\mu^2} \frac{\alpha_s}{\pi}, \quad \delta(\alpha_s, \xi) = \mu^2 d \frac{d}{d\mu^2} \xi, \] (17)

with \( Y = MS \) or RI/SMOM or RI/SMOM\( _{\gamma_R} \).

II. NNLO COMPUTATION

We now compute the conversion factors to \( O(\alpha_s^3) \) in dimensional regularization \( (d = 4 - 2\epsilon) \). Let us denote

\[ \sigma = -4N_c p^2 + \sigma^{(1)} + \sigma^{(2)} + O(\alpha_s^3), \] (18)

\[ \lambda = 4N_c + \lambda^{(1)} + \lambda^{(2)} + O(\alpha_s^3), \] (19)

\[ \lambda = 4d N_c + \lambda^{(1)} + \lambda^{(2)} + O(\alpha_s^3), \] (20)

where the superscripts denote the loop order, \( \sigma^{(1)}, \lambda^{(1)}, \) and \( \lambda^{(1)} \) have been evaluated in [7]. For the present computation, we also need their \( O(\epsilon) \) parts, which will affect the \( O(\alpha_s^3) \) results for \( C_q \) and \( C_m \). Taking the traces and employing partial fractions, we obtain

\[ \sigma^{(1)}(p^2) = 4N_c C_F (p^2 - p^2) = \frac{\alpha_s}{4\pi} (p^2 \gamma_{\epsilon})^\epsilon \]

\[ \times \left\{ \frac{[d + \xi - \frac{3}{2}] g(1, 1) + 1 - \xi}{2} g(2, 1) \right\}, \] (21)

\[ \lambda^{(1)}(p^2, p^2, q^2) = 4N_c C_F \frac{\alpha_s}{4\pi} d - (1 - \xi) \]

\[ \times \left\{ \left \{ \frac{q^2 j(1, 1, 1; p^2, p^2, q^2) + g(1, 1)e^{\gamma_{\epsilon}}}{2} \right \} \right\}, \] (22)

\[ \lambda^{(1)}(p^2, p^2, q^2) = 2N_c C_F \frac{\alpha_s}{4\pi} \left\{ [(d - 2)^2 q^2 - (d - 2) \]

\[ \times (1 - \xi)(p^2 + p^2) \right\} j(1, 1, 1; p^2, p^2, q^2) \]

\[ - 2(d - 2)(1 - \xi) g(1, 1) e^{\gamma_{\epsilon}} \left( \frac{p^2}{q^2} \right)^\epsilon \]

\[ + [2(1 - \xi) g(1, 2) + (d - 2)^2 + (d - 4)(1 - \xi) g(1, 1)] e^{\gamma_{\epsilon}} \]

\[ \times \left\{ \left \{ \frac{q^2 j(1, 1, 1; p^2, p^2, q^2) + g(1, 1)e^{\gamma_{\epsilon}}}{2} \right \} \right\}, \] (23)

where \( \gamma_E \) is the Euler-Mascheroni constant, \( \nu \) is the dimensional renormalization scale, and [13]

\[ g(\nu_1, \nu_2) = \frac{\Gamma(\nu_1 + \nu_2 + \epsilon - 2)\Gamma(2 - \epsilon - \nu_1)\Gamma(2 - \epsilon - \nu_2)}{\Gamma(\nu_1)\Gamma(\nu_2)\Gamma(4 - \nu_1 - \nu_2 - 2\epsilon)}. \] (24)

The function \( j \) results from a massless triangle, via

\[ j(\nu_1, \nu_2, \nu_3; p_1^2, p_2^2, p_3^2) = \left( \frac{i}{16\pi^2} \right)^{-1} \left( \frac{\nu^2}{4\pi^2} \right)^\epsilon \]

\[ \times \int \frac{d^4k}{(2\pi)^d} \left[ (-k^2)^\epsilon \left[ (k + p_1)^2 \right]^\epsilon \left[ (k - p_2)^2 \right]^\epsilon \right], \] (25)

with \( p_3 = -(p_1 + p_2) \). Several cases have been evaluated in [14] (our \( j \) is essentially their \( J \)), in particular

\[ j(1, 1, 1; p_1^2, p_2^2, p_3^2) = \left( \frac{\nu^2}{-p_3^2} \right)^\epsilon \gamma(1 + \epsilon) \phi(1, x, y) \]

\[ + e \psi(1, x, y) + O(\epsilon^2)), \] (26)

where \( x = p_1^2/p_3^2 \) and \( y = p_2^2/p_3^2 \). The functions \( \phi(1, x, y) \) and \( \psi(1, x, y) \) have been given in [14] in terms of polylogarithms up to second and third order, respectively.

At the two-loop level, the relevant diagrams are shown in Fig. 1. They can be represented in terms of three master “topologies” (Fig. 2), which may be called “propagator,” “ladder,” and “nonplanar,” with their propagators raised to general integer powers. For the latter two topologies, irreducible numerators occur. The set can be reduced by standard reduction techniques and a systematic application integration-by-parts (IBP) identities. For this we employ the program FIRE [15], a public implementation of Laporta’s algorithm [16] and the method of S-bases [17].

A subtle aspect of the IBP reduction is the occurrence of quadratic and simple poles in \( \epsilon \) in the coefficients of the

FIG. 1. Two-loop propagator and vertex diagrams. The grey blobs indicate a sum over all one-loop corrections to a propagator; the black boxes indicate an insertion of a fermion bilinear.

FIG. 2. Basic three- and two-point topologies: ladder, nonplanar, propagator (from left to right).
resulting integrals. In a two-loop computation, this leads to poles of up to fourth order. On the other hand, the Feynman diagrams have poles of at most second order, entirely of ultraviolet origin. The spurious third- and fourth-order poles cancel, which constitutes a check of the computation, but they also imply a possible dependence on terms up to $\mathcal{O}(\varepsilon^3)$ in the $\varepsilon$ expansion of the master integrals remaining after the reduction. We find that only known master integrals [14,18,19] are needed. In practice, we employ the $\mathcal{O}(\varepsilon^5)$ part of $j(1, 1 + \varepsilon)$ instead of the results in [19]. Denoting

\[ f(1, 1 + 2 + \varepsilon; p_1^2, p_2^2, p_3^2) = \left(\frac{\varepsilon^2}{\varepsilon^2 - p_3^2}\right)^{1/2} \Gamma(1 + \varepsilon)(-p_3^2)^{-1 - \varepsilon} \frac{1}{2(1 + \varepsilon)xy} \left[-\frac{\pi^2}{6} - 2(\ln^2 x + \ln^2 y) - \ln(\ln y) - 3(1 - x - y) \Phi(1, 1, 1) + \varepsilon^2 \Xi^{(1)}(x, y) + \mathcal{O}(\varepsilon^3)\right], \]

we find

\[ \Xi^{(1)}(x, y) = \frac{1}{2} \Omega^{(2)}(x, y) - \Omega^{(2)}\left(\frac{1}{x}, \frac{1}{y}\right) = -(3 - 6x)\Phi^{(1)}(x, y) + \frac{11}{3} \ln^2 x + 14\zeta(3) + \ln\left(\frac{3 - 6x}{3} \Phi^{(1)}(x, y) - \frac{2}{3} \pi^2\right). \quad (27) \]

The function $\Omega^{(2)}$ arises in evaluating ladder master integrals [14,18] and is given there in terms of polylogarithms. Combining all terms and MS-renormalizing the gauge coupling and gauge parameter, we obtain

\[ C_m^{\text{RI/SOM}}(\omega) = 1 + \frac{\alpha_s}{4\pi} C_F \left[\frac{3 + \xi}{2} \Phi^{(1)}\left(\frac{1}{\omega}, \frac{1}{\omega}\right) - 4 - \xi + 3 \ln \omega\right] + \frac{\alpha_s^2}{4\pi^2} C_F \left[N_c \left(-\frac{2531}{48} - \frac{3\xi}{4} - \frac{\xi^2}{4} + 12\zeta(3)\right) + \frac{307 + 6\xi^2}{12}\ln \omega + \frac{301}{24} + \frac{3\xi^2}{8} - \frac{13 + 2\xi^2}{4}\ln \omega - 7 + 3\xi^2\ln \omega \right] \Phi^{(1)}\left(\frac{1}{\omega}, \frac{1}{\omega}\right) + \frac{9 + 6\xi + \xi^2}{8}\ln r + \frac{9 + 6\xi + \xi^2}{8}\ln r + \frac{3 + \xi}{2}\Phi^{(2)}(1, \omega) - \frac{3 + \xi}{8} \ln \omega \right] \Phi^{(1)}\left(\frac{1}{\omega}, \frac{1}{\omega}\right) + \frac{21 + 6\xi + \xi^2}{4}\ln r - \frac{9}{4}\ln^2 r\]

\[ + \frac{1 + \xi}{2}\Phi^{(2)}\left(\frac{1}{\omega}, \frac{1}{\omega}\right) + \frac{1}{2} \Omega^{(2)}(1, \omega) - \frac{259 - 180\xi + 9\xi^2}{72} \ln \omega + \frac{3 - \xi}{2}\Phi^{(1)}(1, \omega) + \frac{3 - \xi}{8}\ln r + \frac{3 - \xi}{8}\ln r + \frac{\omega}{2}\Phi^{(2)}(1, \omega) \]

\[ + \frac{22(1 - \omega) + 3(1 - \omega) \xi}{12\omega}\ln^2 \omega + \frac{1 + (\omega - 2)\xi}{4\omega} \ln r + \frac{3 - \xi}{8}\ln r + \frac{1}{2}\Phi^{(2)}(1, \omega) \]

\[ + \frac{3 - \omega - \xi}{2\omega}\Phi^{(2)}\left(\frac{1}{\omega}, \frac{1}{\omega}\right) + \frac{5}{36}\ln r + \frac{1 + \xi}{2}\Phi^{(2)}\left(\frac{1}{\omega}, \frac{1}{\omega}\right) \]

\[ + \frac{1}{N_c}\left[\frac{1}{16}\xi + \frac{7}{8}\Phi^{(2)}(1, \omega) - 3(1 - \xi)\Phi^{(1)}(1, \omega) - \frac{6 + \xi}{4}\ln r + \frac{1 - 3\xi + 2\xi^2}{4}\ln \omega + \frac{3 - \xi + 2\xi^2}{4}\Phi^{(2)}(1, \omega) \ln r - \frac{1}{2}\Phi^{(2)}(1, \omega) \right] \ln r \]

\[ - \frac{1 - \xi}{8}\ln^2 \omega + \frac{13}{8} + \frac{1 + \xi}{2}\Phi^{(1)}\left(\frac{1}{\omega}, \frac{1}{\omega}\right) \]

\[ + \frac{1 - \xi}{2}\Phi^{(2)}\left(\frac{1}{\omega}, \frac{1}{\omega}\right) \]

\[ + \frac{1 - \xi}{2}\Phi^{(2)}(1, \omega) - 2(\omega - 2) - \frac{1 - \xi}{2}\Phi^{(1)}\left(\frac{1}{\omega}, \frac{1}{\omega}\right) \]

\[ - \frac{1 - \xi}{2}\Phi^{(2)}(1, \omega) \]
More explicitly, denoting

where \( r = \mu^2/\nu^2 \), \( n_f \) is the number of quark flavors, and \( \Phi^{(3)} \) is given in terms of polylogarithms in [14]. The function \( \Psi^{(1)} \) has dropped out of the final results. We do not know the origin of this cancellation, involving many different terms, including the \( O(\varepsilon) \) one-loop terms. As an \( \varepsilon \) test, setting \( \mu = \nu \) in (29) and taking \( \omega \to 0 \), we recover \( C^{\text{RI/MOM}}_m \) [6,8]. The \( O(\alpha_s) \) terms in (29)–(31) agree with [7] (for \( \omega = 1 \) and \( r = 1 \)). The most general form \( C^{\text{RI/SOMMER}}_m (\omega, \omega') \), defined in (12), can be obtained from (30) and (31) as

The mass and field anomalous dimensions in the two schemes are easily obtained by substituting the expressions (29)–(31), as well as \( C^{\text{SMOM}}_m = C^{\text{RI/MOM}}_m \) [6,8] and the well-known two-loop \( \beta \) function into (14) and (15). More explicitly, denoting

where \( p = m \) or \( p = q \), \( X = \text{RI/SOMM} \) or \( \text{RI/SOMM}_{\gamma_{\mu}} \),

and the remaining coefficients can be read off (29)–(31), we have to NNLO:

\[
\gamma_p = \gamma_p^{\text{SMOM}} + 4\beta^{(0)}C_p^{(1)}\left(\frac{\alpha_s}{4\pi}\right)^2 + 4\beta^{(0)}[2C_p^{(2)} - (C_p^{(1)})^2]
+ 4\beta^{(1)}C_p^{(1)}\left(\frac{\alpha_s}{4\pi}\right)^3 + \Delta_p^X + O(\alpha_s^3). \tag{35}
\]

Here,

which vanishes in the Landau gauge, is again straightforward to evaluate to \( O(\alpha_s^4) \) from (29)–(31) and the perturbation expansion of \( \delta \) defined in (16). Gauge invariance implies \( \delta = \gamma_A \xi \), where \( \gamma_A \) is the anomalous dimension of the gluon field (defined analogously to (16)) [20–22], giving

\[
\delta = \frac{\alpha_s}{4\pi} \xi \left\{ \frac{13 - 3\xi}{6} N_c - \frac{2}{3} n_f \right\}_\gamma + \left(\frac{\alpha_s}{4\pi}\right)^2 \xi \left\{ \frac{59 - 11\xi - 2\xi^2}{8} N_c - \frac{2}{2N_c} n_f \right\}_\gamma + O(\alpha_s^3). \tag{37}
\]
III. PHENOMENOLOGY

To explore the phenomenological consequences of our result for QCD with three dynamical light quarks (as in nature, and in modern unquenched simulations), we set \( n_f = 3 \). Figure 3 shows the conversion factor \( C_m(\omega) \) in the Landau gauge. We observe that the NNLO correction, like the NLO term, is very small at the SMOM point \( \omega = 1 \). This is in contrast to the RI’/MOM scheme \( \omega = 0 \), where even the next-to-next-to-next-to-leading-order (NNNLO) correction [6,8] is large (dot in the figure). To estimate the effects from uncomputed \( O(\alpha_s^3) \) terms, we vary the renormalization scale (matching scale) \( \nu \) used in the conversion and evolve \( C_m^{\text{RI/SMOM}}(\omega = 1; \nu) \) to the fixed scale \( \mu = 2 \) GeV, which gives a formally \( \nu \)-independent number [23,24]. The result is shown in Fig. 4. The width of each band, due to the uncertainty on \( \alpha_s(M_Z) = 0.1184 \pm 0.0007 \) [25], is almost negligible. This is a consequence of the smallness of the NLO and NNLO corrections. We observe that the NNLO result is almost scale-independent. Alternatively, we can convert the \( \overline{\text{MS}} \) mass to the RGI quark mass employing the relevant expressions in [24], which is also scale-independent. The result is similarly stable under scale variation, but the \( \alpha_s \) dependence is a bit more pronounced. A slightly larger residual scale dependence is found for the RI/SMOM\( \gamma_\mu \) scheme. Numerically, we obtain

\[
m_{\overline{\text{MS}}}^{\text{RI/SMOM}}(2 \text{ GeV}) = \left( 0.979^{+0.024}_{-0.010} \, \text{h.o.} 0.001 \right) m_{\text{RI/SMOM}}^{\text{RI/SMOM}}(2 \text{ GeV}),
\]

\[
m_{\text{RI}}^{\text{RI/SMOM}} = \left( 0.932^{+0.030}_{-0.021} \, \text{h.o.} 0.003 \right) m_{\text{RI/SMOM}}^{\text{RI/SMOM}} (2 \text{ GeV}),
\]

\[
m_{\text{RI}}^{\text{RI/SMOM}_\gamma} = \left( 2.53^{+0.07}_{-0.04} \, \text{h.o.} 0.02 \right) m_{\text{RI/SMOM}}^{\text{RI/SMOM}_\gamma} (2 \text{ GeV}),
\]

\[
m_{\text{RI}}^{\text{RI/SMOM}_\gamma} = \left( 2.41^{+0.07}_{-0.04} \, \text{h.o.} 0.03 \right) m_{\text{RI/SMOM}}^{\text{RI/SMOM}_\gamma} (2 \text{ GeV}),
\]

FIG. 3 (color online). Conversion factors \( C_m^{\text{RI/SMOM}} \) as function of \( \omega = q^2/p^2 \) at LO (top/red), NLO (middle/blue), and NNLO (bottom/black), and \( C_m^{\text{RI/SMOM}} = C_m^{\text{RI/SMOM}_\gamma} = 0 \) at NNLO (dot).

FIG. 4 (color online). Residual matching-scale dependence of the conversion factor \( C_m^{\text{RI/SMOM}} \) at \( \omega = 1 \) at LO (red), NLO (blue), and NNLO (black).

The width of each band, due to the uncertainty on \( \alpha_s(M_Z) = 0.1184 \pm 0.0007 \) [25], is almost negligible. This is a consequence of the smallness of the NLO and NNLO corrections. We observe that the NNLO result is almost scale-independent. Alternatively, we can convert the \( \overline{\text{MS}} \) mass to the RGI quark mass employing the relevant expressions in [24], which is also scale-independent. The result is similarly stable under scale variation, but the \( \alpha_s \) dependence is a bit more pronounced. A slightly larger residual scale dependence is found for the RI/SMOM\( \gamma_\mu \) scheme. Numerically, we obtain

\[
m_{\overline{\text{MS}}}^{\text{RI/SMOM}}(2 \text{ GeV}) = \left( 0.979^{+0.024}_{-0.010} \, \text{h.o.} 0.001 \right) m_{\text{RI/SMOM}}^{\text{RI/SMOM}}(2 \text{ GeV}),
\]

\[
m_{\text{RI}}^{\text{RI/SMOM}} = \left( 0.932^{+0.030}_{-0.021} \, \text{h.o.} 0.003 \right) m_{\text{RI/SMOM}}^{\text{RI/SMOM}} (2 \text{ GeV}),
\]

\[
m_{\text{RI}}^{\text{RI/SMOM}_\gamma} = \left( 2.53^{+0.07}_{-0.04} \, \text{h.o.} 0.02 \right) m_{\text{RI/SMOM}}^{\text{RI/SMOM}_\gamma} (2 \text{ GeV}),
\]

\[
m_{\text{RI}}^{\text{RI/SMOM}_\gamma} = \left( 2.41^{+0.07}_{-0.04} \, \text{h.o.} 0.03 \right) m_{\text{RI/SMOM}}^{\text{RI/SMOM}_\gamma} (2 \text{ GeV}),
\]

corresponding to a perturbative uncertainty of less than 2%, or about 2 MeV, for the strange quark mass, when converting from the RI/SMOM scheme, and about 3% for the RI/SMOM\( \gamma_\mu \) scheme. As the absolute size of the NLO and NNLO corrections is also larger for the RI/SMOM\( \gamma_\mu \) scheme, we advocate the use of the RI/SMOM scheme together with an appropriate error estimate in extracting results for the light-quark masses.

IV. CONCLUSION

We have computed the RI/SMOM \( \rightarrow \overline{\text{MS}} \) and RI/SMOM\( \gamma_\mu \rightarrow \overline{\text{MS}} \) conversion factors for the quark mass to NNLO and shown that the RI/SMOM and RI/SMOM\( \gamma_\mu \) schemes, designed to reduce sensitivity to low-energy nonperturbative physics, are perturbatively very well behaved, too. These schemes thus may be used to extract quark masses with percent-level accuracy from numerical lattice QCD. An important question is whether the same holds true for other quantities of interest, such as \( B_K \) and other hadronic matrix elements.

ACKNOWLEDGMENTS

We are happy to thank Chris Sachrajda for a talk and conversations raising our interest in the topic, and him and Andrzej Buras for comments on the manuscript. M. G. thanks the Galileo Galilei Institute for hospitality and the INFN for support during a stay.

Note added.— After the initial submission of this manuscript to the arXiv, Ref. [26] appeared, whose authors compute the conversion factor \( C_m \) at NNLO for the symmetric renormalization point \( \omega = 1 \), where they confirm our result. They also give the corresponding field \( C_q^{\text{RI/SMOM}\gamma_\mu} \) and mass conversion factors \( C_q^{\text{RI/SMOM}\gamma_\mu} \) and \( C_q^{\text{RI/SMOM}_\gamma} \).
for the RI/SMOM\(_r\) scheme, as well as expressions for the NNLO anomalous dimensions in both schemes. In this revised version, we have given expressions for those quantities, as well. Specializing to \(\omega = \omega' = r = 1\), our results for the \(c^X_q\) agree with the results in [26]. Setting further \(\xi = 0\), we agree with the results for \(\gamma^X_q\) given there, up to a global sign difference [27].

[23] We use the program RUNDEC for the running of \(\alpha_s\) at the appropriate order and for decoupling heavy quarks at their thresholds. The program is described in Ref. [24].
[27] We thank the authors of [26] for correspondence in which they informed us that this disagreement is due to a typo in that paper, which is rectified in the journal version.
