Cobalt(II/III), nickel(II) and copper(II) coordination clusters employing a monoanionic Schiff base ligand: synthetic, topological and computational mechanistic aspects†

Edward Loukopoulos,a Benjamin Berkoff,a Kieran Griffiths,a Victoria Keeble,a Vassiliki N. Dokorou,a Athanassios C. Tsipis,*b Albert Escuer and George E. Kostakis*a

Nine mono-, di- and tetranuclear coordination clusters (M = CoII/III, NiII, CuII) using a monoanionic Schiff base ligand were synthesized and characterized by X-ray crystallography. A series of transformations occur in the ligand in certain compounds for which theoretical studies are presented. Synthetic aspects, topological issues and magnetic studies are discussed.

Introduction

Despite the long history and activity of polynuclear metal complexes, also known as coordination clusters (CCs),† their coordination chemistry continues to be a field that attracts great interest today. Among the different categories of ligands used in this field, perhaps one of the most significant is Schiff bases, which have received a large amount of attention especially in the past decade. This is due to their wide range of useful properties such as strong biological activity,2–4 ease of access and versatile coordination abilities. As a result, CCs using ligands of this nature are of special importance and many examples of their applications in materials science,5–7 catalysis,8–12 biological processes,13–15 molecular magnetic materials,16–21 photochemistry,24,25 and nanostructure studies26,27 have been explored.

In particular, Schiff bases formed from o-vanillin as starting material have been of significant interest and their coordination abilities along with various metal centres have been investigated thoroughly, leading to very interesting results.28–41 For example, the usage of a Schiff base formed between L-glutamic acid and o-vanillin along with Ni(NO3)2·6H2O results in an intriguing 15-nickel metallomacrocyclic complex.31 Ferromagnetic and ferroelectric properties were observed in two enantiomerically pure nanoscale manganese CCs supported by chiral Schiff base ligands,29 while the pentanuclear compound Mn3CaIIINaI appeared to be a sufficient catalyst for water oxidation.42

Scheme 1 The protonated form of (E)-4-(2-hydroxy-3-methoxybenzylideneamino)-2,3-dimethyl-1-phenyl-1,2-dihydro- pyrazol-5-one (HL1) ligand used in this study. The different transformations of the HL1 ligand observed in compounds 5–7 (H2L2, H3L3, H2L4). Transformed organic molecules are presented in their protonated form.
However, according to a CSD search, all previously reported o-vanillin-based Schiff base ligands used for the synthesis of polynuclear CCs were derived mainly through a condensation of o-vanillin along with either amino alcohol such as 2-aminoethanol or amino acid to produce di- or triprotic organic species. Based on this observation, we recently decided to study the coordination abilities of a Schiff base ligand derived from the condensation of o-vanillin and 4-aminooantipyrine and named $(E)-4-[2$-hydroxy-3-methoxybenzylideneamino]-2,3-dimethyl-1-phenyl-1,2-dihydropyrazol-5-one (HL$_1$, Scheme 1).

Despite providing similar coordination modes to other diprotic ligands, i.e. those derived from o-vanillin and 2-aminoethanol or 2-aminoenophenol, HL$_1$ is monoanionic and thus is anticipated to lead to unprecedented topologies. Indeed, the employment of HL$_1$ in Co$^{III}$Dy$^{III}$ chemistry and thus present the synthesis, characterization and crystal structure of nine CCs formulated as \( [\text{Co}^{II}L_2]^2\text{MeCN} \) ($1$-5MeCN), \( [\text{Ni}^{II}L_2]^2\text{MeCN} \) ($2$-5MeCN), \( \text{Cu}^{II}L_2\text{MeCN} \) ($3$-MeCN), \( [\text{Co}^{II}L_4(\text{MeO}_2)]^2\text{(ClO}_4) \) ($4$), \( [\text{Co}^{II}L_4(\text{H}_2\text{O})] \) ($5$), \( [\text{Co}^{II}L_4(\text{MeO}_2)]^2\text{MeCN} \) ($6$), \( [\text{Co}^{II}L_4]^{2-}\text{MeCN} \) ($7$-2MeCN), \( [\text{Ni}^{II}L_3(\text{MeOH})]\text{(ClO}_4)\text{2MeOH} \) ($8$-2MeOH), and \( [\text{Cu}^{II}L_4(\text{MeO}_2)]^2\text{ClO}_4\text{6MeOH} \) ($9$-6MeOH) as well as the magnetic properties for representative compounds 4 and 8. Synthetic and topological issues are discussed. In addition, we report interesting cases of ligand transformation found in 4-7 supported by theoretical density functional theory studies, which give valuable insight into the direct mechanism taking place during these transformations.

**Experimental**

**Materials and methods**

**Materials.** Chemicals (reagent grade) were purchased from Sigma-Aldrich and Alfa Aesar. All experiments were performed under aerobic conditions using materials and solvents as received. Safety note: Perchlorate salts are potentially explosive; such compounds should be used in small quantities and handled with caution and utmost care at all times.

**Instrumentation.** IR spectra of the samples were recorded over the range 4000–650 cm$^{-1}$ on a PerkinElmer Spectrum One FT-IR spectrometer fitted with a UATR polarization accessory. Elemental analysis data were recorded at Science Centre, London Metropolitan University, 29 Hornsey Road, London N7 7DD, UK.

**Magnetic studies.** Magnetic susceptibility measurements were carried out on polycrystalline samples with a Quantum Design MPMS5 susceptometer working in the range 30–300 K under an external magnetic field of 0.3 T and under a field of 0.03 T in the 30–2 K range to avoid saturation effects. Diamagnetic corrections were estimated from Pascal tables.

**Computational details.** All calculations were performed using the Gaussian 09 program suite. The geometries of all stationary points located on the potential energy surfaces (PESs) were fully optimized without symmetry constraints, employing the 1997 hybrid functional of Perdew, Burke, and Ernzerhof as implemented in the Gaussian 09 program suite. This functional uses 25% so-called “exact” exchange, i.e. Hartree–Fock-like exchange built on Kohn–Sham orbitals, $E_{HF}^*$, 75% (“pure DFT”) GGA exchange in the PBE approximation, $E_{GGA}^*$, and 100% GGA correlation in the PBE formulation, $E_{c}^{PBE}$, and is denoted as PBE0. For the geometry optimizations we have used the Def2-TZVP basis set for Co atoms and the 6-31G(d,p) basis set for all main group elements (E).

**Synthetic procedures**

**Ligand synthesis.** The synthesis of HL$_1$ has been carried out according to the reported synthetic procedure.

**Synthesis of [Co$^{II}L_2]^2$-5MeCN (1-5MeCN).** 0.55 mmol (0.190 g) of HL$_1$ and 0.55 mmol (77.1 μL of Et$_3$N were dissolved in 20 ml of MeCN. The resulting yellow solution was brought to reflux and stirred for 10 minutes. To this, 0.23 mmol (0.050 g) of CoBr$_2$ were added and the resulting red solution was refluxed for another 20 minutes, filtered, and then kept in a vial and subjected to slow evaporation. Red crystals formed within 1 day. Yield: 35% (based on Co).

**Synthesis of [Ni$^{II}L_2]^2$-5MeCN (2-5MeCN).** 0.25 mmol (0.084 g) of HL$_1$ and 0.25 mmol (34.9 μL of Et$_3$N were dissolved in 20 ml of MeCN while stirring to produce a yellow solution. To this, 0.1 mmol (0.037 g of Ni(ClO$_4$)$_2$6H$_2$O were added. The resulting yellow solution was stirred for a further 15 minutes, filtered, and then kept in a vial and stored at room temperature. Large green needles were obtained after 2 days.

**Synthesis of [Cu$^{II}L_4(\text{MeO}_2)]^2$-6H$_2$O (3).** In this study, the initial employment of HL$_1$ in Co$^{II}$, Ni$^{II}$ and Cu$^{II}$ chemistry and thus present the synthesis, characterization and crystal structure of nine CCs formulated as \( [\text{Co}^{II}L_2]^2\text{MeCN} \) ($1$-5MeCN), \( [\text{Ni}^{II}L_2]^2\text{MeCN} \) ($2$-5MeCN), \( \text{Cu}^{II}L_2\text{MeCN} \) ($3$-MeCN), \( [\text{Co}^{II}L_4(\text{MeO}_2)]^2\text{ClO}_4 \) ($4$), \( [\text{Co}^{II}L_4(\text{H}_2\text{O})] \) ($5$), \( [\text{Co}^{II}L_4(\text{MeO}_2)]^2\text{MeCN} \) ($6$), \( [\text{Co}^{II}L_4]^{2-}\text{MeCN} \) ($7$-2MeCN), \( [\text{Ni}^{II}L_3(\text{MeOH})]\text{(ClO}_4)\text{2MeOH} \) ($8$-2MeOH), and \( [\text{Cu}^{II}L_4(\text{MeO}_2)]^2\text{ClO}_4\text{6MeOH} \) ($9$-6MeOH) as well as the magnetic properties for representative compounds 4 and 8. Synthetic and topological issues are discussed. In addition, we report interesting cases of ligand transformation found in 4-7 supported by theoretical density functional theory studies, which give valuable insight into the direct mechanism taking place during these transformations.
Synthesis of [Cu\textsuperscript{II}L\textsubscript{4}\textsuperscript{−}MeCN (3·MeCN)]. 0.25 mmol (0.084 g) of HL\textsuperscript{−} and 0.5 mmol (69.0 μL of Et\textsubscript{3}N were dissolved in 20 ml of MeCN while stirring to produce a yellow solution. To this, 0.1 mmol (0.020 g) of Cu(OAc)\textsubscript{2}·H\textsubscript{2}O were added. The resulting dark brown solution was stirred for a further 15 minutes, filtered, and then kept in a vial and stored at room temperature. Dark brown block crystals were obtained after 1 day. Yield: 45% (based on Cu). Selected IR peaks (cm\textsuperscript{−1}): 2932 (w), 2830 (w), 1662 (s), 1583 (s), 1538 (m), 1492 (m), 1456 (s), 1434 (m), 1389 (m), 1298 (m), 1242 (m), 1208 (s), 1155 (w), 1109 (m), 1073 (s), 1043 (s), 976 (s), 928 (w), 878 (w), 850 (w), 820 (w), 789 (m), 742 (s), 707 (s), 688 (m). Elemental analysis for C\textsubscript{30}H\textsubscript{39}CuN\textsubscript{7}O\textsubscript{6}·H\textsubscript{2}O·MeCN·H\textsubscript{2}O·MeOH·Et\textsubscript{3}N·2H\textsubscript{2}O: calcd. C 61.67, H 5.27, N 12.51.

Synthesis of [Co\textsuperscript{II}L\textsubscript{4} (MeOH)\textsubscript{2}·2(ClO\textsubscript{4})·2MeCN (4)]. 0.25 mmol (0.084 g) of HL\textsuperscript{−} and 0.25 mmol (34.9 μL) of Et\textsubscript{3}N were dissolved in 20 ml of MeOH while stirring to produce a yellow solution. To this, 0.1 mmol (0.037 g) of Co\textsuperscript{II}(OAc)\textsubscript{2}·6H\textsubscript{2}O were added. The resulting red solution was stirred for a further 15 minutes, filtered, and then kept in a vial and stored at room temperature. Red prismatic crystals were obtained after 5 days. Yield: 25% (based on Co). Selected IR peaks (cm\textsuperscript{−1}): 2935 (w), 2817 (w), 1603 (s), 1583 (s), 1558 (m), 1544 (m), 1489 (w), 1456 (s), 1433 (s), 1391 (m), 1241 (m), 1213 (s), 1194 (m), 1081 (s), 1036 (s), 969 (s), 913 (w), 869 (w), 855 (w), 788 (m), 741 (s), 701 (s), 677 (m).

Synthesis of [Co\textsuperscript{II}L\textsubscript{4}·(H\textsubscript{2}O)\textsubscript{2}]·5MeCN (5). 0.30 mmol (0.100 g) of HL\textsuperscript{−} and 0.30 mmol (41.8 μL) of Et\textsubscript{3}N were dissolved in 20 ml of MeCN while stirring to produce a yellow solution. To this, 0.24 mmol (0.060 g) of Co(OAc)\textsubscript{2}·4H\textsubscript{2}O were added. The resulting red solution was stirred for a further 20 minutes, filtered, and then kept in a vial and stored at room temperature. Red block crystals were obtained after 3 days. Yield: 20% (based on Co). Selected IR peaks (cm\textsuperscript{−1}): 2935 (w), 2817 (w), 1603 (s), 1583 (s), 1558 (m), 1544 (m), 1489 (w), 1479 (m), 1440 (s), 1404 (m), 1311 (m), 1235 (m), 1209 (s), 1072 (s), 1024 (s), 971 (s), 877 (w), 857 (w), 787 (w), 738 (s), 722 (s), 684 (m).

Synthesis of [Co\textsuperscript{II}L\textsubscript{4}·(H\textsubscript{2}O)\textsubscript{2}]·6H\textsubscript{2}O (6). Method 1: (6) was prepared in the same ratio and solvent as (3) by using Co(OAc)\textsubscript{2}·4H\textsubscript{2}O and then carefully layering the solution over Et\textsubscript{3}N at a respective ratio of 1:2. Red block crystals were obtained after 1 day. Yield: 35% (based on Co). Selected IR peaks (cm\textsuperscript{−1}): 2935 (w), 2828 (w), 1621 (s), 1592 (s), 1558 (m), 1484 (m), 1445 (s), 1403 (s), 1307 (m), 1239 (m), 1210 (s), 1074 (s), 1026 (s), 967 (s), 875 (w), 856 (w), 811 (w), 737 (s), 719 (s), 690 (m). Method 2: 0.56 mmol (0.190 g) of L and 1.11 mmol (154.3 μL) of Et\textsubscript{3}N were dissolved in 20 ml of MeCN. The resulting yellow solution was brought to reflux and stirred for 10 minutes. To this, 0.46 mmol (0.157 g) of Co(ClO\textsubscript{4})\textsubscript{2}·6H\textsubscript{2}O were added and the resulting red solution was refluxed for another 20 minutes, filtered and kept in a vial and subjected to slow evaporation. Red crystals formed within 1 day. Yield: 20% (based on Co). Method 3: 0.56 mmol (0.190 g) of L and 2.21 mmol (308.6 μL) of Et\textsubscript{3}N were dissolved in 20 ml of MeCN. The resulting yellow solution was brought to reflux and stirred for 10 minutes. To this, 0.45 mmol (0.166 g) of Co(ClO\textsubscript{4})\textsubscript{2}·6H\textsubscript{2}O were added and the resulting red solution was refluxed for another 20 minutes, filtered and kept in a vial and subjected to slow evaporation. Red crystals formed within 1 day. Yield: 20% (based on Co). Elemental analysis for C\textsubscript{76}H\textsubscript{76}Co\textsubscript{4}N\textsubscript{12}O\textsubscript{24}: calcd. C 51.37, H 4.31, N 9.46; found C 51.40, H 4.18, N 9.44.

Crystallography

Data for 1, 2, 3, 5, 6, 9 and 10 were collected (ω-scans) at the University of Sussex using an Agilent Xcalibur Eos Gemini Ultra diffractometer with a CCD plate detector under a flow of nitrogen gas at 173(2) K using Mo Kα radiation (λ = 0.71073 Å). Crystals were used for data collection and processing, respectively. Reflection intensities were corrected for absorption by the multi-scan method. Data for 4, 7 and 8 were collected at the National
Crystallography Service, University of Southampton. All structures were determined using Olex2, solved using either Superflip or SHELXT and refined with SHELXL-2014. All non-H atoms were refined with anisotropic thermal parameters, and H atoms were introduced at calculated positions and allowed to ride on their carrier atoms. In compounds 8 and 9, atoms of minor components (several with partial occupancy) were sensibly refined isotropically. Crystal data and structure refinement parameters for all compounds are given in Tables S1 and S2.

† Geometric/crystallographic calculations were performed using PLATON, Olex2, and WINGX packages; graphics were prepared with Crystal Maker and MERCURY.

Results and discussion

Crystal structure description

Compounds 1–3 are monomers synthesized using a 4 : 5 : 5, 2 : 5 : 10 or 2 : 5 : 5 metal–ligand–base ratio and acetonitrile as solvent (Fig. 1). All compounds crystallize in the triclinic P1 space group and contain one molecule in the asymmetric unit. Compounds 1 and 2 are isostructural and thus only the former will be further described. Compound 1 is a CoII monomer in which the metal centre has a distorted octahedral geometry, coordinating to two ligand molecules and a total of 6 atoms. Each ligand coordinates to CoII via the phenoxide oxygen atoms (O2 and O5), the imine group nitrogen atoms (N1 and N4) and the carbonyl group oxygen atoms (O3 and O6) (Scheme S1,† mode A). The mean M–Ophenoxide distances are 2.0076(17) and 2.0141(16) Å, while the M–Nimine distances were measured at 2.0873(19) and 2.0855(18) Å. M–Ocarbonyl distances are slightly longer at 2.2458(16) and 2.2286(16) Å, respectively, indicative of a CoII. Similar bond distances for 2 can be found in the ESI† (Table S3). Five acetonitrile molecules are also present in the crystal lattice. As in 1 and 2, no hydrogen bonding or other supramolecular interaction can be found within the crystal structure.

Compound 3 is a Cu monomer in which the metal centre coordinates to two ligand molecules and a total of 4 atoms, having a distorted square planar geometry. Each ligand coordinates to CuII via the phenoxide oxygen atoms (O2 and O5) and the imine group nitrogen atoms (N1 and N4) (Scheme S1,† mode B). The mean M–Ophenoxide distances are 1.8991(13) Å and 1.9006(14) Å, while the M–Nimine distances were measured at 1.9671(14) and 1.9532(17) Å, all slightly lower than the respective distances in compounds 1 and 2. One acetonitrile molecule is also present in the crystal lattice. As in 1 and 2, no hydrogen bonding or other supramolecular interaction can be found within the crystal structure.

Compound 4 is synthesized using a 2 : 5 : 5 metal–ligand–base ratio and methanol as solvent and crystallizes in the monoclinic P21/c space group. The asymmetric unit contains

Fig. 1 (Left) The structure of compounds 1 and 2. M = CoII (1), NiII (2). (Right) The structure of compound 3. H atoms and solvent molecules are omitted for clarity. Colour code: M, grey; Cu, light blue; O, red; C, black; N, blue.

Fig. 2 The structure of compounds 4 (top) and 5 (middle). Symmetry operations: (i) 1 − x, 3/2 − y, z; (ii) 5/4 − y, 1/4 + x, 1/4 − z; (iii) y − 1/4, 5/4 − x, 1/4 − z. (Bottom) The structure of compound 6. Symmetry operations: (i) 1 − x, 3/2 − y, z; (ii) y − 1/4, 5/4 − x, 5/4 − z; (iii) 5/4 − y, 1/4 + x, 5/4 − z. H atoms and lattice molecules are omitted for clarity. Colour code: Co, purple; O, red; C, black; N, blue.
four metal centres, four ligand molecules, two bridging methoxides and two perchlorate counter ions (Fig. 2, top).

The main core of the cluster is a deformed cubane-like Co₄O₈ consisting of four CoII centres, two bridging μ₃-O methoxido atoms, and two bridging μ₂-O phenoxido atoms. Each of the CoII centres coordinates to six atoms and displays a distorted octahedral geometry. The four organic ligands exhibit two different coordination modes, two ligands per mode. In the first mode, the phenoxy oxygen atom and the imine nitrogen atom coordinate to one CoIII centre, while the carbonyl oxygen atom coordinates to a second CoII centre (Scheme S1,† mode C). In the second mode, one CoII centre is coordinated to the phenoxy oxygen atom, the imine nitrogen atom and the carbonyl oxygen atom, while the phenoxy atom is further bridging two CoII centres and the methyl ether group oxygen atom also coordinates to the third CoII centre (Scheme S1,† mode D). The CoII...CoIII distances range from 3.018(7) to 3.350(7) Å. Selected bond lengths and angles are given in Table S10.† No hydrogen bonds or other supramolecular interactions can be found between the molecules within the crystal structure.

Compound 5 is synthesized using a 4 : 5 : 5 metal–ligand–base ratio and acetonitrile as solvent (Fig. 2, middle). As in 4, a Co₄O₈ cubane-like core is formed; however, a transformation of the ligand has taken place. The CH₂ group of the C atom of the pyrazolone ring is oxidized to a CH₂OH, as confirmed by X-ray crystallography (Scheme 1, H₂L₄). Compound 5 has crystallographically imposed 4 symmetry and crystallizes in the tetragonal I4₁/̅a space group and the asymmetric unit consists of one CoII centre, one L₃ ligand and one water molecule. There are no solvent molecules or counter ions present in the structure. The cubane-like Co₄O₈ consists of the four CoII and four bridging μ₂-O methoxido atoms of the CH₂OH transformed group. Only one type of coordination mode is present in the structure, as the ligand coordinates to the metal centre via the imine nitrogen atom (N1), the phenoxy oxygen atom (O2) and an oxygen atom (O4) (Scheme S1,† mode H).

A water molecule also coordinates to each of the cobalt centres to fulfill the distorted octahedral geometry. The mean M–Nᵦᵦ distance was measured at 2.107(3) Å. Co...Co distances range from 3.2207(11) to 3.2277(9) Å. Additional bond distances and angles are given in Table S10.† The crystal structure of 6 is stabilized by a strong O–H...O intermolecular hydrogen bond, which involves a water oxygen atom (O6) as a donor and a carbonyl oxygen atom (O3) as an acceptor. The structure is further stabilized by a strong O–H...O intramolecular hydrogen bond within two ligands, in which an oxygen atom of the transformed group (O5) participates as a donor. The parameters of these hydrogen bonds are listed in Table S5.†

Compound 7 was synthesized using a 4 : 5 : 5 metal–ligand–base ratio and acetonitrile as solvent (Fig. 3). It crystallizes in the triclinic P1 space group and contains two molecules in the asymmetric unit. Unlike the three previous structures, bond valence sum (BVS) calculations are indicative of oxidation state III for both Co centres (3.22 for Co1 and 3.24 for Co2). The ligand undergoes another oxidation (H₂L₄, Scheme 1) and the methyl group connected to the pyrazolone ring is transformed to a carboxylate, as assigned by the 1.234(5) Å and 1.275(4) Å bond distances for C31–O7 and C31–O6, respectively. Each molecule contains a CoIII centre, one L¹ ligand and one L⁴ ligand as well as two acetonitrile solvent.
molecules. The Co\textsuperscript{III} centre has a distorted octahedral geometry and is coordinated to one L\textsuperscript{1} molecule via the phenoxide oxygen atom, the imine group nitrogen atom and the carboxyl group oxygen atom (Scheme S1,\textsuperscript{1} mode A) as well as one L\textsuperscript{4} molecule via the imine nitrogen atom, the phenoxide oxygen atom and the carboxyl group oxygen atom (Scheme S1,\textsuperscript{1} mode I). The mean M–N\textsubscript{imine} distances are relatively similar for both ligands (1.929(3) Å for L\textsuperscript{4} coordination, 1.933(3) and 1.937(3) Å for L\textsuperscript{1} coordination), while the M–O\textsubscript{phenoxide} distances are smaller in the case of the L\textsuperscript{1} ligand (1.869(3) Å for L\textsuperscript{1} coordination, 1.873(3) and 1.885(3) Å for L\textsuperscript{4} coordination). The mean M–O\textsubscript{carboxyl} distances are 1.970(3) and 1.985(3) Å, significantly larger than the M–O\textsubscript{carboxyl} distances which were measured at 1.904(3) and 1.912(3) Å. Two acetonitrile molecules are also present in the crystal lattice. As in the previous monomeric compounds (1–3), there are no hydrogen bonds or other supramolecular interactions formed between the molecules within the crystal structure.

Compound 8 is a Ni dimer, synthesized using a 2:5:5 metal–ligand–base ratio and methanol as solvent (Fig. 4). It crystallizes in the monoclinic I2/c space group and contains one molecule in the asymmetric unit. Each nickel centre is coordinated to six atoms and displays a distorted octahedral geometry. There are three ligand molecules in the structure and each exhibits a different coordination mode (Scheme 1,\textsuperscript{1} modes A, E, and F). Ni1 is coordinated to two ligands, while Ni2 is coordinated to all three. In detail, Ni1 is coordinated to the carboxyl oxygen atom of one ligand (O6) and the imine nitrogen atoms (N4, N7) as well as the phenoxide oxygen atoms (O5, O8) of two ligand molecules. A terminal methanol solvent molecule also coordinates to the metal centre through the oxygen atom O10. Ni2 is coordinated to phenoxide oxygen atoms from all three ligands (O2, O5, O8), the imine nitrogen atom and the phenoxide oxygen atom of one ligand (N1 and O3, respectively), as well as the methyl ether group oxygen atom of a second ligand molecule (O4). Out of the respective Ni–O distances, Ni2–O4 was the longest and was measured at 2.295(3) Å, while Ni1–O5 was the shortest at 1.984(3) Å. Comparing the respective Ni–N distances, the mean Ni1–N4 distance was the longest at 2.085(3) Å, while Ni2–N1 was the shortest at 2.020(3) Å. Selected bond lengths and angles are given in the ESI\textsuperscript{†} (Table S6). Two perchlorate counter ions are also present in the structure along with two lattice solvent molecules. The crystal structure of 8 is stabilized by strong O–H⋯O intermolecular hydrogen bonds, which are formed between either two lattice methanol molecules or one lattice methanol and a perchlorate anion. Further stabilization occurs with the formation of a strong O–H⋯O intramolecular hydrogen bond within the ligands. The parameters of these hydrogen bonds are listed in Table S7.\textsuperscript{†}

**Topological features**

HL\textsuperscript{1} offers similar coordination environment to other diprotic ligands; however, in order to identify its unique and different coordination abilities we performed an extended literature CSD search\textsuperscript{43} seeking the coordination abilities of any ligand that resembles those in Scheme 2, bottom. Then, we further categorized these findings employing our topological approach to describe CCs,\textsuperscript{69} which resulted in a library of all CCs with nuclearity over 3 (ESI,\textsuperscript{†} Excel). The library consists of 100 CCs possessing 29 different motifs. Only 28 entries contain solely 3d (Mn, Fe, Co, Ni and Cu) metal centres. Utilizing HL\textsuperscript{1} along with Co\textsuperscript{III} and Cu\textsuperscript{II}, in methanolic solution, results in cubane Co\textsuperscript{II} (4) and Cu\textsuperscript{II} (9) structures (3M4–1, Scheme 2),\textsuperscript{69} in the presence of MeO bridges, and along with Ni(ClO\textsubscript{4})\textsubscript{2}·6H\textsubscript{2}O in a Ni\textsuperscript{III} dimer (8) (1M2–1, Scheme 2). In contrast, the reaction of diprotic ligands with Ni results in a Ni\textsuperscript{II}.
The reaction in protic solvent affords compounds of both the metal and the ligand, indicating sensitivity to oxidation. The transformation of the perchlorate anion to a chloride anion is not unusual and has been seen before. More crystallographic data are necessary to perform a complete structural comparison; however, the present findings indicate that HL, despite offering similar coordination sites to other similar diprotic ligands, coordinates completely different from them and thus its coordination chemistry can lead to new, interesting and unprecedented topologies.

**Synthetic issues**

A detailed analysis of the synthetic aspects for the afforded compounds 1–6 provides very interesting points. There are a few parameters that influence the resulting structures. Among these parameters are a) the solvent which was used, b) the temperature in which the syntheses took place and c) the metal source used. From the resulting compounds it becomes evident that these attributes not only affect the metal nuclearity and the coordination modes of the ligand to the metal centres but also facilitate the ligand transformations which were observed in compounds 4–7. With regard to the solvent which was used, the afforded compounds can be divided into two categories: a) those which were obtained using a polar solvent such as methanol (compounds 4, 8, 9) and b) those which were obtained using a non-polar solvent, i.e. acetonitrile (compounds 1–3, 5–7). An immediate observation is the change in the metal nuclearity which also seems to be connected to the ligand transformations; the reaction in protic solvent affords compounds of both the metal and the ligand, indicating sensitivity to oxidation. The transformation of the perchlorate anion to a chloride anion is not unusual and has been seen before. More crystallographic data are necessary to perform a complete structural comparison; however, the present findings indicate that HL, despite offering similar coordination sites to other similar diprotic ligands, coordinates completely different from them and thus its coordination chemistry can lead to new, interesting and unprecedented topologies.

### Computational mechanistic studies

A comprehensive and consistent picture of the transformations that the coordinated ligands to Co complexes under study undergo (cf. Scheme 1) has been derived by means of DFT calculations employing the PBE0/Def2-TZVP(Co) \( \cup \) 6-31G(d,p,E) \( \{E = \text{main group element}\} \) computational protocol. All crucial reaction steps have been scrutinized by examining the participation of Co-O\(_2\) intermediates in terms of located structures, energies and activation barriers. First we calculated the equilibrium geometries and the electronic

structure of the “free” ligands $L^n (n = 1–4)$ in MeCN solutions. Fig. 5 shows the ground-state geometries of the “free” ligands $L^n$, the natural atomic charges on selected atoms and the frontier molecular orbitals relevant to coordination of the ligands in MeCN solutions calculated by the PBE0/6-31G(d,p)/PCM computational protocol.

Perusal of the highest occupied molecular orbitals (HOMOs) of the “free” $L^n$ ligands reveals that the electron density is primarily localized on the phenoxide moieties including also the localization on the 2p AOs of the O and N donor atoms of the ligands. These atoms acquire negative natural atomic charges, namely $-0.667–0.722$ on the phenoxide O atom, $-0.592–0.677$ on the carboxyl group O atom, $-0.526–0.531$ on the methoxide O atom and $-0.514–0.576$ on the imine group nitrogen atom. Both the nature of the HOMOs and the negative natural atomic charges show that all these atoms could participate in the coordination of the $L^n$ ligands to the Co central atom, thus explaining all coordination modes observed experimentally (Scheme S1†).

To probe the “distant” intramolecular C–H bond activation by the coordinated superoxide ligand of the C–H bonds of the –CH$_3$, –CH$_2$OH and –CH(OH)$_2$ substituents on the C atom of the pyrazolone ring of the ligands $L^n$ that promotes the $L^1 \rightarrow L^2 \rightarrow L^3 \rightarrow L^4$ ligand transformations, the reaction trajectory was explored through DFT calculations of the potential energy surfaces (PESs) and monitoring the geometric and energy reaction profiles (Fig. 6–8). A possible reaction mechanism is shown in Scheme 3.

In the first step, the [L$^n$Co$^{II}$]$^{n+}$ complexes interact with dioxygen forming the superoxo [L$^n$Co(O–O$^-$)]$^{n+}$ adducts. The formation of the superoxo [L$^n$Co(O–O$^-$)]$^{n+}$ adducts correspond to exothermic processes, and the estimated exothermicities are around $-18.1–18.5$ kcal mol$^{-1}$ at the PBE0/Def2-TZVP(Co $\cup$ 6-31G(d,p)(E)/PCM level of theory. In the superoxo [L$^n$Co(O–O$^-$)]$^{n+}$ complexes, the spin density, which was localized at the metal centre in the precursor [L$^n$Co$^{II}$]$^{n+}$ complexes, is now localized at the superoxide ligand (Scheme 4).

An inspection of Fig. 6–8 reveals that the [L$^n$Co$^{II}$]$^{n+}$ (n = 1–3) complexes of Co$^{II}$ in their doublet ground states bind O$_2$ in an asymmetric side-on $\eta^2$-O$_2$ coordination mode with an O–O bond length of 1.28 Å, intermediate between the values of 1.21 Å for O$_2$ and 1.34 Å for O$_2^{2-}$. This bonding mode involving a one-electron transfer from the Co$^{II}$ metal centre to the dioxygen ligand gives rise to the formation of superoxo [L$^n$Co(O–O$^-$)]$^{n+}$ complexes. In the superoxo [L$^n$Co(O–O$^-$)]$^{n+}$ complexes the Co–O bond lengths for the shorter Co–O bonds are 1.866, 1.839, 1.827 and 1.822 Å for the $L^1$Co(O–O$^-$)]$^{n+}$, $L^2$Co(O–O$^-$)]$^{n+}$, $L^3$Co(O–O$^-$)]$^{n+}$ and $L^4$Co(O–O$^-$)]$^{n+}$ complexes,
defined as superoxo or peroxy complexes, respectively, based primarily on the X-ray structural data (O–O bond distance) and vibrational spectra (O–O stretching frequency, νO–O).75–79

In particular, when the O–O bond length is ≈ 1.4–1.5 Å and the νO–O ≈ 800–930 cm⁻¹ the compounds are designated as peroxides, whereas when O–O ≈ 1.2–1.3 Å and νO–O ≈ 1050–1200 cm⁻¹ the compounds are characterized as superoxides. In the model [L³Co(O–O⁻)]⁺ complexes the O–O bond length of 1.28 Å and the unscaled νO–O stretching vibrational frequencies around 1299–1317 cm⁻¹ illustrate their superoxo character. Although for the superoxide ligand the more common coordination is the end-on coordination (η¹-O²⁻) it is also well-coordinated in the side-on fashion (η²-O²⁻), respectively. An analogous reaction trajectory was proposed by Wada and co-workers for the stoichiometric oxidation of the coordinated superoxo radical abstracts a hydrogen atom through a homolytic C–H bond cleavage (H- transfer) supported by both electrostatic and orbital interactions. An intramolecular electrophilic attack of the C atom of the –CH₃ and –CH₂OH groups by the negatively charged coordinated superoxo radicals is precluded due to the negative natural atomic charges bearing the C atoms of these groups (−0.775 and −0.167|e|, respectively). The orbital interactions supporting the hydrogen transfer in the [L³Co(O–O⁻)]⁺ complexes correspond predominantly to HOMO-6 ↔ LUMO and HOMO-7 ↔ LUMO interactions (Scheme 4). After the hydrogen abstraction of the C–H bond, a homolytic O–O bond cleavage (O–O homolysis) in the CoIII–OOH species takes place, affording Co³⁺ = O (−Co⁵⁺OH⁴⁻) and HO⁻ radical, which attacks the C atoms of the CH₃, CH₂OH and CH(OH)₂ groups in a nearly concerted fashion (OH hydroxylation), yielding the hydroxylated ligands L², L³ and L⁴ predominantly (Fig. 6–8). Furthermore, the active Co³⁺ = O (−Co⁵⁺OH⁴⁻) species generated after the homolytic O–O bond cleavage could perform cooperatively a second C–H bond cleavage step (H- transfer) yielding the [L³Co(OH)] (n = 2–4) intermediates, which subsequently are transformed to the [L²Co(OH₂)]⁶⁺, [L²Co(OH₃)]²⁺ and [L¹L⁴Co] products. These transformations are predicted to be highly exothermic; the estimated exothermicities are −190.0, −203.1 and −202.0 kcal mol⁻¹ for the L¹ → L², L² → L³ and L³ → L⁴ ligand transformations, respectively. The superoxo [L³Co(O–O⁻)]⁺ complexes are transformed to [L²Co(OH)] (n = 2–4) intermediates through the [[L²Co(O₂)]³⁺ transition states surmounting an activation barrier of 52.9, 44.3 and 42.4 kcal mol⁻¹ for the L¹ → L², L² → L³ and L³ → L⁴ ligand transformations, respectively. The lowering of the activation barrier along the L¹ → L², L² → L³ and L³ → L⁴ ligand transformations could be attributed to the increase in the electrophilic character of the C atom of the –CH₃, –CH₂OH and –CH(OH)₂ groups, which facilitates the ‘OH hydroxylation process. An analogous reaction trajectory was proposed by Wada and co-workers for the stoichiometric oxidation of

respectively, and for the longer Co–O bonds are 1.931, 1.914, 1.930 and 1.937 Å, respectively.

It is worth noting that in 1:1 metal–O₂ complexes both the end-on (η¹-) and the side-on (η²-) bonding modes have been identified so far and the corresponding adducts were

substrates by the non-heme mononuclear hydroperoxo–Fe$^{III}$ complex and more recently by Li et al.$^{53}$ in the proposed mechanism of dioxygen-activating non-heme enzymes.

**Magnetic studies**

The room temperature $\chi T$ value for compound 4 under an applied field of 3000 G is 8.64 cm$^3$ K mol$^{-1}$ which is higher than that of the spin only value of 7.48 cm$^3$ K mol$^{-1}$ for four Co$^{II}$ (Co$^3_2$; $S = 3/2$ and $g = 2.0$). The $\chi T$ value gradually decreases with decreasing temperature, reaching a plateau at around 10–20 K and then sharply falls down to 5.17 cm$^3$ K mol$^{-1}$ at 1.8 K. (Fig. 9). The non-continuous $\chi T$ decay evidences some coupling inside the cube in addition to the usual $D_{ion}$. To have a rough approach to the Co$^{II}$…Co$^{II}$ interactions, fitting of the experimental data was performed with the PHI program,$^{84}$ assuming a distorted cube of four $S = 3/2$ spins on the basis of the Hamiltonian $H = -J_1(S_1S_1 + S_2S_2) - J_2(S_1S_2 + S_1S_3) - J_3(S_1S_3 + S_2S_3)$, which corresponds to a cube with similar interactions in opposite faces. Taking into account a $D_{ion}$ term, an excellent fit was obtained for the parameters $J_1 = +4.4$ cm$^{-1}$, $J_2 = +1.3$ cm$^{-1}$, $J_3 = -1.4$ cm$^{-1}$, $g = 2.12$ and $D_{ion} = 18.8$ cm$^{-1}$. The positive $J_1$ interaction can be assigned to the pair of faces with smaller Co–Co bond angles, close to 94–95°. Magnetization experiments performed at 2 K show a constant increase of magnetization up to a quasi-saturated value equivalent to 5.91 electrons under the maximum external field of 5 T, (Fig. 9, inset). Each Co$^{II}$ can be treated as an effective $S = 1/2$ spin at low temperature due to the ZFS, and thus the magnetization must behave as a strongly anisotropic effective $S = 2$ spin level. The fit of the magnetization, assuming the above response, gives an excellent agreement for $D_{ex} = 2 = -1.7$ cm$^{-1}$ and $g = 3.10$.

The room temperature $\chi M T$ value for compound 8 is 2.57 cm$^3$ K mol$^{-1}$, which is higher than that of the spin only value of 2.33 cm$^3$ K mol$^{-1}$ for two Ni$^{II}$ (Fig. 10). Upon cooling, this value starts to increase to a maximum value of 2.62 cm$^3$ K mol$^{-1}$ at 20 K and then decreases to 1.68 cm$^3$ K mol$^{-1}$ at 2 K. Magnetization measurements show a continuous increase of magnetization up to a maximum value equivalent to 3.2 electrons. This behavior suggests weak ferromagnetic coupling with an $S = 2$ ground state and a significant $D$ contribution. Simultaneous fit of the experimental data was performed, applying the Hamiltonian $H = -J(S_1S_2)$ and including a $D_{ion}$ parameter. Least-squares fitting of the experimental data gave the common values of $J = +1.2$ cm$^{-1}$, $g = 2.255$, $D = 3.79$ cm$^{-1}$ for both measurements. The fit confirms an $S = 2$ ground state for 8.

**Conclusions**

In this work we have successfully, for the first time, employed the monoanionic Schiff base ligand (HL$^1$, Scheme 1) derived from the condensation of o-vanillin and 4-aminantipyrine in cobalt, nickel and copper chemistry to access nine new CCs. A topological evaluation of all polynuclear CCs obtained is reported. In addition, a structural comparison of the present polynuclear CCs along with the compounds derived from structurally related ligands is attempted (Scheme 2). We conclude that a) HL$^1$ coordinates completely different from them and thus its coordination chemistry can lead to new, interesting and unprecedented topologies and b) more synthetic studies are required to reach a point wherein the design of such species can be undertaken.$^{85}$ In addition, we report interesting cases of ligand transformations (Scheme 1), which take place in certain experiments with cobalt sources (4–7). These transformations occur in one of the methyl groups of the pyrazolone ring of the HL ligand under specific conditions such as the use of a particular metal salt, ratio and solvent, altering drastically the coordination mode of the ligand and resulting in different structures. DFT calculations of the potential energy surfaces (PESs) and monitoring the geometric and energetic reaction profiles of the intramolecular $L^1 → L^2 → L^1 → L^2 → L^1$ ligand transformations revealed a possible reaction mechanism that involves the formation of super-oxo [$L^1Co(O−O^−)$]$^+$ adducts, which are transformed to [$L^1Co(OH)$]$^+$ (n = 2–4) intermediates through the [$[L^1Co(OH)]$]$^+$ transition states, surmounting an activation barrier of 52.9, 44.3 and 42.4 kcal mol$^{-1}$ for the $L^1 → L^2$, $L^2 → L^1$ and $L^1 →$...
