Synthesis of unsymmetrical NCN′ and PCN pincer palladacycles and their catalytic evaluation compared with a related SCN pincer palladacycle†‡

Gavin W. Roffe,a Graham J. Tizzard,b Simon J. Coles,b Hazel Coxa and John Spencer*a

1-(3-(Pyridin-2-yl)phenyl)methanamine derivatives have been synthesized and underwent C–H bond activation to afford unsymmetrical NCN′ pincer palladacycles, which were characterised in the solid state. 2-Pyridinyl-phenol and -benzyl alcohols were then used as precursors to unsymmetrical PCN pincer palladacycles. Catalytic applications, where the palladacycle remains in the Pd(II) state, have been carried out and show good activity and selectivity.

Introduction

Palladacycles contain a covalent Pd–C bond intramolecularly stabilised by a coordinating group such as an amine, phosphine or thioether and have been extensively studied since their discovery in the mid-1960s.1 Pincer palladacycles, where a tridentate ligand can coordinate to palladium were first synthesised by Shaw and Moulton in 1976.2 However, the field of palladacycle-mediated catalysis only truly gathered momentum after the seminal discovery by Herrmann and Beller et al.3,4 that their eponymous palladacycle (Fig. 1) was highly active in catalytic C–C bond coupling reactions. Since, a number of reviews and books have been published covering the wide array of catalytic applications.5–14

The majority of pincer palladacycles are symmetrical, such as I (Fig. 2).15 However, unsymmetrical analogues such as II (Fig. 2),16 have been explored,17 and may provide a greater opportunity to fine tune catalysis due to the potential hemilability of the ligand18 and the ability to influence catalytic activity by altering the steric and electronic properties of the donor atoms.19,20

The synthesis of NCN pincers can be complicated compared with the analogous PCP and SCS pincers due to the hard-ligand (amine) soft-acid (metal) mismatch between palladium and nitrogen. This results in competition in forming the kinetic product III or the thermodynamic pincer product IV (Scheme 1).21 Hence, incorporating functional groups in the mutual ortho position such as SiMe3 or Br can be beneficial in their synthesis, compared with C–H activation routes.8 However, this is less attractive synthetically, since an additional step is required in making the functionalised ligand.

Examples of unsymmetrical PCN pincer palladacycles (Fig. 3) are synthesised by C–H bond activation or chloropalla-
A potential route to phosphorus containing palladacycles is via phenolic or benzylic alcohols, such as that by Eberhard et al., in the formation of mixed 5-,6-membered PCP', and 5-,5-pincer palladacycles (Fig. 3) containing both phosphine and phosphinite groups. Palladacycles normally act as a reservoir of catalytically active Pd(0) species in applications such as the Suzuki–Miyaura/Heck reaction. Other catalytic applications of pincer palladacycles utilise the palladium in its Pd(II) oxidation state, retaining its ligand structure, and are more likely to take advantage of the tuning abilities of the unsymmetrical ligand design. The use of pincer palladacycles as a Lewis acid catalyst in an aldol condensation (Scheme 2) demonstrated the ability to change the stereochemical outcome of the reaction depending on the ligand donor atoms. Another application utilising pincer palladacycles in Pd(II) catalysis, is in the coupling of vinyl epoxides and boronic acids using a symmetrical SeCSe palladacycle (Scheme 3).

Results and discussion
NCN' ligand synthesis
The simple biaryl motif 1 was deemed to be a potentially useful precursor to NCN’ pincer ligands. 1 was formed via a Suzuki–Miyaura (SM) coupling and several catalysts, Pd(PPh3)4, Pd(dppf)Cl2, Pd(OAc)2 and Buchwald’s XPhos Pd G2 catalyst were trialled in order to optimise its yield (Table 1). It was found that Pd(dppf)Cl2 (Pd-118) was the catalyst of choice utilising microwave-mediated (MW) synthesis (Scheme 2).

Reductive amination of 1 with HNMe2·HCl was attempted in order to synthesise the requisite unsymmetrical NCN’ ligand with the dimethyl amine and pyridine groups ideally placed to promote C–H activation towards the corresponding palladacycle. Initially sodium triacetoxyborohydride proved unsuccessful although the use of titanium isopropoxide/sodium borohydride furnished the product 2a in 81% yield (Scheme 4). Next, we attempted reductive aminations with NET3H using both of the above conditions but to no avail.

dation. A potential route to phosphorus containing palladacycles is via phenolic or benzylic alcohols, such as that by Eberhard et al., in the formation of mixed 5-,6-membered PCP', and 5-,5-pincer palladacycles (Fig. 3) containing both phosphine and phosphinite groups. Results and discussion
NCN' ligand synthesis
The simple biaryl motif 1 was deemed to be a potentially useful precursor to NCN’ pincer ligands. 1 was formed via a Suzuki–Miyaura (SM) coupling and several catalysts, Pd(PPh3)4, Pd(dppf)Cl2, Pd(OAc)2 and Buchwald’s XPhos Pd G2 catalyst were trialled in order to optimise its yield (Table 1). It was found that Pd(dppf)Cl2 (Pd-118) was the catalyst of choice utilising microwave-mediated (MW) synthesis (Scheme 2).

Reductive amination of 1 with HNMe2·HCl was attempted in order to synthesise the requisite unsymmetrical NCN’ ligand with the dimethyl amine and pyridine groups ideally placed to promote C–H activation towards the corresponding palladacycle. Initially sodium triacetoxyborohydride proved unsuccessful although the use of titanium isopropoxide/sodium borohydride furnished the product 2a in 81% yield (Scheme 4). Next, we attempted reductive aminations with NET3H using both of the above conditions but to no avail.
Given that the reductive amination procedure proved ineffectual, an alternative synthesis was devised. In previous work,29 we have shown the synthesis of the benzyl bromide 4, via benzyl alcohol 3 (Scheme 5) can allow late stage diversification via nucleophilic substitution by sulphur nucleophiles.25 Hence, the corresponding nucleophilic displacement of 4 was undertaken with nitrogen nucleophiles, yielding NCN' ligands 2b and 2c in excellent yield (Scheme 5).

NCN' palladacycle synthesis

Ligands 2a–c were then selected for C–H activation towards the palladacycle products. Refluxing the ligand in AcOH in the presence of Pd(OAc)₂, followed by salt metathesis yielded the desired monomeric palladacycles 5a–e (Scheme 6).

The yields for forming these palladacycles are disappointing, due to significant formation of Pd black, and therefore an optimisation study for the synthesis of 5c was attempted (Table 2). Changing the solvent to MeOH (entry 2), the palladium source to in situ generated Pd(MeCN)₄(BF₄)₂ (entry 3),33 and a transcyclopalladation (entry 4)34 using Pd₂(dmba)(μ-Cl)₂ (Table 2) were attempted. It was found that indeed, the initial Pd(OAc)₂ in AcOH method proved to be the most effective for palladation (entry 1).

However, literature yields for NCN pincers are often low, with several examples provided using Pd(OAc)₂ as the palladium source (Table 3), showing the wide range of yields achieved for the key C–H bond activation step from the corresponding NCN pincer ligands. Shaw’s earlier work, in contrast, showed yields for PCP pincers of around 75%.²

In order to delve into such poor yields, we looked at the stability of 5c in refluxing d₄ acetic acid over time via ¹H NMR, which showed no degradation of the palladacycle over time, under the conditions used for C–H activation. We also contemplated an oxidative addition of a Pd[0] salt to a bromide,38 although attempts to ortho-brominate 2c were unsuccessful.

PCN palladacycle synthesis

The synthetic route to unsymmetrical NCN’ pincer palladacycles has been modified to provide a route to unsymmetrical PCN pincer palladacycles. The synthesis of phosphinite palladacycles has been shown by Eberhard et al.39 from a benzyl alcohol using CIPR₂, and therefore the benzyl alcohol 3 was used as the starting point for synthesis of a PCN pincer palladacycle. Due to the air sensitivity of the PCN ligand, after
reaction with ClPPh2, C–H bond activation using Pd(OAc)2 in AcOH was performed in situ (Scheme 8). This synthesis yields a mixed 5-,6-membered palladacycle, and for direct comparison with our 5-,5-membered SCN,29 and NCN′ pincer palladacycles, a phenolic alcohol was synthesised (Scheme 7). Using the phenolic (6) and benzylic alcohols (3), the synthesis of PCN pincer palladacycles was undertaken (Scheme 8). The PCN pincer palladacycle structures were also confirmed using X-ray crystallography (Fig. 5).

Growth of crystals of 5a–c and 7a and 7b by slow evaporation of CH2Cl2 from a saturated solution allowed their structures to be determined by X-ray diffraction (Fig. 4 and 5). All structures were as expected, with the metal in a distorted square planar arrangement.

Compound 5a crystallises in the monoclinic P21 space group with two independent molecules in the asymmetric unit. These are subject to π–π interactions (benzene centroid-pyridine centroid distances: 3.564 Å and 3.715 Å, offsets: 1.301 Å and 1.386 Å respectively). These pairs of molecules form layers with a ‘herringbone’ arrangement propagating along the crystallographic b and c axes.

The structure 5b crystallises in the monoclinic P21/c space group with two independent molecules in the asymmetric unit. The structure is formed from corrugated layers of molecules propagating along the crystallographic a and b axes with each alternate layer consisting of the same crystallographically-independent molecules.

The structure 5c crystallises in the monoclinic P21/n space group. The structure consists of π–π stacks (benzene centroid–pyridine centroid distances: 3.616 Å and 3.705 Å, offsets: 1.319 Å and 1.617 Å respectively) along the crystallographic c axis formed of alternating molecules related by inversion. There are weak C–H...O (C2–O1 = 3.458(3) Å and C8–O1 = 3.371 (3) Å) interactions between the stacks which lead to the formation of corrugated layers along the a and b axes.

Fig. 5 PCN pincer palladacycle crystal structures of (i) 7a, and (ii) 7b.
Fig. 6 Previously published SCN pincer palladacycle by our group.

Structure 7a crystallises in the monoclinic P21/n space group. The structure consists of columns of molecules close-packed along the crystallographic 21 screw axis parallel to the b axis with π–π interactions to neighbouring columns via the phenyl pyridine moieties (centroid–centroid distance: 3.894 Å, offset: 1.322 Å).

Structure 7b crystallises in the lower symmetry triclinic, P1 space group. The structure is comprised of close-packed discrete layers parallel to the ac plane. These layers in turn are made up of close-packed ‘chains’ of C–H⋯O (C19⋯O1 = 3.405(2) Å) dimers with π–π interactions between neighbouring dimers via the phenyl pyridine moieties (centroid–centroid distance: 3.653 Å, offset: 1.098 Å). Structures 5a–c and 7a–b were given CCDC numbers 1038592, 1038593, 1038594, 1476634 and 1476635 respectively.

**Catalytic investigation**

Next, 5c, 7a and 7b were tested in the catalytic aldol condensation (Scheme 2) and compared with a previously published SCN pincer palladacycle (8) by our group (Fig. 6)35 along with commercially available PdCl2(dtbbp) and Pd(OAc)2. The results are presented in Table 4, alongside the published data by Szabó and co-workers for symmetrical PCP and SCS pincer palladacycles, as well an unsymmetrical PCS pincer palladacycle (Scheme 2).27

a Performed in duplicate, average of 2 runs. trans/cis ratio determined by crude 1H NMR of the resulting mixture. Reaction conditions: methylisocyanacetate (1 eq.), benzaldehyde (1 eq.), 1Pr3EtN (0.1 eq.), [Pd] (1 mol%), DCM (5 cm³), 24 h, rt. b Scheme 2.

The results presented in Table 4 show that the family of palladacycles synthesised by our group, with SCN, NCN’ and PCN examples, provides the opportunity to fine tune catalytic activity, with the choice of donor group influencing the stereochemical outcomes of the aldol condensation. The novel PCN pincer palladacycle 7a provides the highest trans selectivity of all catalysts tested, and slightly more than the literature PCP example, whereas the SCN and NCN’ provide a greater proportion of the cis product.27

In addition, catalysis of the coupling of a vinyloxirane and phenylboronic acid was tested, using the NCN’, SCN and PCN pincer palladacycles, and compared to literature SeCSe results shown in Fig. 7.28 and our new results using the symmetrical SCS palladacycle (Scheme 2). The coupling and results are presented in Table 5.

The results presented in Table 5 show that the symmetrical pincer palladacycles, SeCSe and SCS achieve the greatest linear selectivity (>78%), whereas the unsymmetrical pincer palladacycles achieve a higher proportion of the branched product (>34%). Clearly the presence of unsymmetrical pincer palladacycles is having an effect of the stereochemical outcome of the reaction, increasing the proportion of the branched product.

**Conclusions**

The simple synthesis of three NCN’ ligands has been shown. Their C–H activation yielded three new NCN’ pincer palladacycles. Similarly, two novel PCN pincer palladacycles were syn-
thesised, with 5,5-, and 5,6-membered rings and all palladacycles were characterised by X-ray crystallography.

The catalytic applications of the NCN, SCN and PCN pincer palladacycles, along with several other examples were considered in two Pd(II)-mediated reactions, an aldol condensation and vinyl epoxide coupling. It was found that in the aldol condensation, the ability to fine tune the stereochemical outcome of the reaction is possible, by varying the donor atoms in the palladacycle catalyst. It was also shown in the vinyl epoxide coupling that the unsymmetrical pincer palladacycles achieve different product ratios than the symmetrical palladacycles tested, demonstrating the potential benefits of unsymmetrical palladacycles in catalytic applications.

Further work is being undertaken towards varying the families of unsymmetrical palladacycles, supported by DFT investigations into their bonding properties and reactivity. Moreover, it is hoped that such simple synthetic routes to unsymmetrical pincer ligands may encourage others to employ these in other areas of transition metal chemistry and catalysis.

**Experimental**

**General details**

Solvents and chemicals were purchased from commercial suppliers and used without further purification, with reactions taking place open to atmosphere and moisture.

**Instrumentation**

1H and 13C spectra were recorded on either a Varian 400 or 500 MHz spectrometer. HRMS were obtained on an ESI mass spectrometer using a Bruker Daltonics Apex III, with source Apollo ESI, using methanol as the spray. Flash chromatography was performed on an automated ISCO RF75. GC measurements were obtained using a Perkin Elmer Autosystem XL Gas Chromatograph, utilizing a flame ionization detector, and a Supelco MDN-5S 30 m × 0.25 mm × 0.25 μm column, with a He mobile phase. Elemental analyses were run by the London Metropolitan University Elemental Analysis Service. Crystal structures were obtained by the UK National Crystallography Service at the University of Southampton.40

3-(Pyridin-2-yl)benzaldehyde (1). [3-Formylphenyl]boronic acid (4.24 mmol, 635 mg), 2-bromopyridine (4.24 mmol, 0.412 cm²), Pd(dppf)Cl₂ (0.17 mmol, 122 mg), 1 M Na₂CO₃ (5 cm³), toluene (10 cm³) and EtOH (5 cm³) were added to a sealed microwave vial and irradiated (maximum power 300 W, dynamic heating) for 20 minutes at 150 °C. The reaction mixture was filtered over celite, the solvent was removed in vacuo. The crude mixture was dissolved in H₂O (25 cm³) and ethyl acetate (25 cm³), extracted with ethyl acetate (2 × 25 cm³), washed with H₂O (2 × 25 cm³) and brine (25 cm³). The organic layers were dried over anhydrous MgSO₄, filtered, and the solvent was removed in vacuo. The crude product was purified using flash column chromatography (7:3 CH₂Cl₂:ethyl acetate) yielding 402 mg of the expected product 1 as a yellow oil in 74% yield. 1H NMR (500 MHz, chloroform-d) δ 10.13 (s, 1H), 8.74 (d, J = 4.8 Hz, 1H), 8.52 (s, 1H), 8.30 (d, J = 7.7 Hz, 1H), 7.94 (d, J = 7.7 Hz, 1H), 7.82–7.79 (m, 2H), 7.65 (dd, J = 7.7, 7.7 Hz, 1H), 7.32–7.28 (m, 1H). 13C NMR (126 MHz, chloroform-d) δ 192.2, 155.9, 149.9, 140.3, 137.0, 136.9, 132.7, 129.7, 129.5, 128.4, 122.8, 122.0. HRMS. Calcd for [C₁₄H₁₂NO + H]+ 259.0757. Found 259.0761.

N,N-Dimethyl-1-(3-(pyridin-2-yl)phenyl)methanamine (2a). 3-(Pyridin-2-yl)benzaldehyde (1) (5.76 mmol, 1.06 g), HNMe₂·HCl (12.1 mmol, 987 mg), Ti(OiPr)₄ (11.6 mmol, 33.0 g) and EtOH (50 cm³) were added to a round bottom flask and stirred at rt overnight. NaBH₄ (8.63 mmol, 327 mg) was then added to the flask and the mixture was stirred at rt for 24 hours. The reaction mixture was quenched using aqueous ammonia (35% in H₂O, 30 cm³) and filtered. The solid residue was washed with CH₂Cl₂ (50 cm³) and the product was extracted from the filtrate using CH₂Cl₂ (3 × 35 cm³). The organic layers were dried over anhydrous MgSO₄ and the solvent was removed in vacuo yielding 0.99 g of the expected product 2a as a green oil in 81% yield. 1H NMR (400 MHz, chloroform-d) δ 8.62 (d, J = 3.8 Hz, 1H), 7.91 (s, 1H), 7.84 (d, J = 7.5 Hz, 1H), 7.67–7.60 (m, 2H), 7.38–7.31 (m, 2H), 7.12–7.10 (m, 1H), 3.45 (s, 2H), 2.20 (s, 6H). 13C NMR (126 MHz, chloroform-d) δ 157.4, 149.5, 139.4, 136.6, 129.7, 128.6, 127.6, 125.7, 122.0, 120.6, 64.3, 45.3 (2C). 1 carbon missing. HRMS. Calcd for [C₁₄H₁₂NO⁺NH₃]⁺ 213.1386. Found 213.1384.

N,N-Diethyl-1-(3-(pyridin-2-yl)phenyl)methanamine (2b). 2-(3-Bromomethyl)phenylpyridine (3) (2.78 mmol, 690 mg), diethylamine (4.17 mmol, 0.43 cm³), K₂CO₃ (12.1 mmol, 1.67 g) and THF (8 cm³) were added to a microwave vial and then stirred under microwave irradiation (maximum power 300 W, dynamic heating) at 150 °C for 30 minutes. The cooled reaction mixture was added to H₂O (25 cm³) and the crude product was extracted using ethyl acetate (3 × 25 cm³), washed with H₂O (2 × 25 cm³) and brine (25 cm³). The combined organic layers were dried over anhydrous Na₂SO₄, filtered and solvent removed in vacuo yielding 665 mg of the expected product 2b as a yellow oil in 99% yield. 1H NMR (500 MHz, chloroform-d) δ 8.69 (d, J = 4.8 Hz, 1H), 7.94 (s, 1H), 7.86 (ddd, J = 5.3, 5.3, 1.9 Hz, 1H), 7.75–7.74 (m, 2H), 7.43–7.41 (m, 2H), 7.24–7.20 (m, 1H), 3.66 (s, 2H), 2.56 (q, J = 7.1 Hz, 4H), 1.06 (t, J = 7.1 Hz, 6H). 13C NMR (100 MHz, chloroform-d) δ 157.7, 149.6, 140.7, 139.3, 136.6, 129.5, 128.5, 127.4, 125.3, 121.9, 120.6, 57.6, 46.8 (2C), 11.8 (2C). HRMS. Calcd for [C₁₆H₁₄NO⁺NH₃]⁺ 241.1699. Found 241.1692.

4-(3-(Pyridin-2-yl)benzyl)morpholine (2c). Same method used as 2a. 638 mg of the expected product 2c was obtained as a yellow oil in quantitative yield. 1H NMR (500 MHz, chloroform-d) δ 8.70 (d, J = 4.9 Hz, 1H), 7.96 (s, 1H), 7.87 (ddd, J = 7.2, 1.7, 1.7 Hz, 1H), 7.77–7.73 (m, 2H), 7.45–7.40 (m, 2H), 7.23 (ddd, J = 7.4, 4.9, 2.4 Hz, 1H), 3.72 (t, J = 4.6 Hz, 4H), 3.59 (s, 2H), 2.48 (t, J = 4.6 Hz, 4H). 13C NMR (100 MHz, chloroform-d) δ 157.5, 149.7, 139.5, 138.2, 136.8, 129.9, 128.8, 127.9, 126.0, 122.2, 120.8, 67.0 (2C), 63.5, 53.7 (2C). HRMS. Calcd for [C₁₄H₁₄NO⁺H₂O]⁺ 255.1492. Found 255.1484.

**Palladacycle (5a).** N,N-Dimethyl-1-(3-(pyridin-2-yl)phenyl)methanamine (2a) (0.80 mmol, 170 mg) and Pd(OAc)₂...
(0.83 mmol, 186 mg) were dissolved in AcOH (15 cm³) and stirred at reflux (125 °C) for 3 hours. The solvent was removed in vacuo, and reconcentrated with CH₂Cl₂ (5 × 50 cm³) to remove any residual acetic acid. The crude mixture was dissolved in MeOH (10 cm³) and LiCl (excess) was added. The mixture was stirred at rt for 30 min. The solvent was removed in vacuo, and the crude mixture dissolved in CH₂Cl₂ (25 cm³) and H₂O (25 cm³). The crude product was extracted using CH₂Cl₂ (2 × 25 cm³), washed with H₂O (3 × 25 cm³). The combined organic layers were dried over MgSO₄, filtered and the solvent removed in vacuo. The mixture was purified by recrystallisation from CH₂Cl₂/hexane yielding 82 mg of the expected product 5a as a yellow solid in 10% yield. ¹H NMR (500 MHz, chloroform-δ) δ 9.06 (d, J = 5.6 Hz, 1H), 7.80 (dd, J = 7.6, 5.6 Hz, 1H), 7.09 (dd, J = 7.6, 7.6 Hz, 1H), 6.92 (dd, J = 7.6, 7.6 Hz, 1H), 4.13 (s, 2H), 3.08 (s, 6H). ¹³C NMR (126 MHz, chloroform-δ) δ 165.1, 163.6, 152.4, 144.5, 142.4, 138.7, 124.8, 123.6, 122.6, 121.2, 118.5, 69.9, 62.8 (2C), 59.64 (2C). HRMS. Calcd for [C₁₆H₁₉N₂OPd]+ 359.0370. Found 359.0359. Anal. Calcd for [C₁₆H₁₉N₂OPdCl]: C, 48.63; H, 4.34; N, 7.09. Found: C, 48.59; H, 4.42; N, 6.97.

3-(Pyridin-2-yl)phenol (6). 3-[Hydroxyphenyl]boronic acid (3.59 mmol, 496 mg), 2-bromopyridine (3.59 mmol, 0.342 mmol), Pd[PPh₃]₄ (0.14 mmol, 164 mg), K₂PO₃ (7.16 mmol, 1.52 g), H₂O (10 cm³), toluene (7.5 cm³) and EtOH (5 cm³) were added to a sealed 35 cm³ microwave vial and stirred under microwave irradiation (maximum power 300 W, dynamic heating) at 150 °C for 20 min. The reaction was cooled, and the solvent removed in vacuo. The mixture was diluted with H₂O (25 cm³) and Et₂O (25 cm³), washed with H₂O (2 × 25 cm³) and brine (25 cm³). The combined organic layers were dried over anhydrous MgSO₄, filtered, and concentrated with CH₂Cl₂ (25 cm³) yielding 103 mg of the expected product 6 as a yellow solid in 10% yield. ¹H NMR (500 MHz, chloroform-δ) δ (ppm): 9.51 (d, 1H), 8.63 (d, J = 4.4 Hz, 1H), 7.86–7.83 (m, 2H), 7.51 (s, 1H), 7.47 (d, J = 7.9 Hz, 1H), 7.34–7.32 (m, 1H), 7.24 (dd, J = 7.9, 7.9 Hz, 6.83 (d, J = 7.9 Hz, 1H). ¹³C NMR (126 MHz, chloroform-δ) δ (ppm): 158.2, 156.5, 149.9, 140.5, 137.6, 130.2, 123.0, 120.6, 117.7, 116.5, 113.8. HRMS. Calcd for [C₁₁H₁₄NO + H]+ 172.0757. Found 172.0755.

Palladacycle (7a). Under an argon atmosphere 3-(pyridin-2-yl)phenylmethanol (418 mg, 2.26 mmol), NEt₃ (0.63 cm³, 4.52 mmol), and DMAP (spatula tip) were dissolved in Et₂O (5 cm³) and cooled to 0 °C. CIPPH₃ (0.41 cm³, 2.22 mmol) was added dropwise to the solution forming a white precipitate. The reaction was warmed to room temperature and stirred for 3 h. The crude mixture was filtered under an argon atmosphere and the solvent removed in vacuo. Pd(OAc)₂ (687 mg, 3.06 mmol) was added to the crude intermediate, dissolved in AcOH (5 cm³), and heated at reflux o/n. The solvent was removed in vacuo and reconstituted with CH₂Cl₂ to remove residual AcOH. NaCl (1.16 g, 19.9 mmol) was added to the crude mixture, which was then dissolved in MeCN (10 cm³) and H₂O (10 cm³), and stirred at room temperature o/n. The solvent was removed in vacuo, and the crude mixture dissolved in CH₂Cl₂ and separated using a hydrophobic frit. The crude product was purified using flash column chromatography (7 : 3 CH₂Cl₂ : EtOAc) yielding 383 mg of the expected product 7a as a yellow solid in 29% yield. ¹H NMR (500 MHz, chloroform-δ) δ (ppm): 9.38 (s, 1H), 8.08–8.03 (m, 4H), 7.88–7.79 (m, 2H), 7.63 (d, J = 7.6 Hz, 1H), 7.52–7.44 (m, 6H), 7.30 (d, J = 6.6 Hz, 1H), 7.19 (dd, J = 7.6, 7.6 Hz, 1H), 7.03 (d, J = 6.6 Hz, 1H), 4.83 (d, J = 19.6 Hz, 2H). ¹³C NMR (126 MHz, chloroform-δ) δ (ppm): 163.3, 151.9, 149.4, 148.2, 139.2 (2C), 136.5, 133.2 (d, J = 158.9 Hz, 133.0 (d, J = 158.9 Hz, 2C), 131.7 (d, J = 158.9 Hz, 128.4 (d, J = 158.9 Hz, 128.3 (d, J = 158.9 Hz, 125.4, 124.1, 122.5 (d, J = 158.9 Hz, 127.1 (d, J = 158.9 Hz, 31P NMR (162 MHz, chloroform-δ) δ (ppm): 123.27. HRMS. Calcd for [C₂₂H₁₉NOPd]+ 474.0239.

4.13 (s, 2H, linear), 3.88 (s, 2H), 7.88 (d, 7.8 Hz, 1H), 7.72 (d, 7.8 Hz, 1H), 7.54–7.46 (m, 5H), 7.34 (s, 1H), 7.29–7.26 (m, 2H), 7.15 (dd, 7.8, 7.8 Hz, 1H), 6.96 (d, 7.8 Hz, 1H). 13C NMR (500 MHz, chloroform-d) δ (ppm): 164.5 (d, 3JPC = 3.0 Hz), 162.6 (d, 3JPC = 10.0 Hz), 149.5, 145.8, 139.3, 133.2 (d, 3JPC = 55.2 Hz), 132.1 (d, 3JPC = 2.5 Hz), 131.6 (d, 3JPC = 14.8 Hz), 128.9 (d, 3JPC = 11.9 Hz), 126.9, 123.1 (d, 3JPC = 3.4 Hz), 119.0, 118.0, 113.5 (d, 3JPC = 17.2 Hz), 107.1. 31P NMR (162 MHz, chloroform-d) δ (ppm): 155.3.

Aldol condensation reaction

Under an argon atmosphere, the palladium catalyst (0.01 eq.) and benzaldehyde (1 eq.) and DIPEA (0.1 eq.) were added to the reaction vessel. The reaction was stirred at rt for 24 h, then the reaction diluted with DCM (10 cm3), washed with H2O (10 cm3), and the organic layer collected using a hydrophobic frit. The solvent was removed in vacuo, and the mixture of products was obtained as a brown oil. 1H NMR (500 MHz, chloroform-d) δ 7.47–7.27 (m, 12H), 5.75 (d, J = 11.1 Hz, 1H, cis), 5.70 (d, J = 7.8 Hz, 1H, trans), 5.10 (dd, 11.1, 2.0 Hz, 1H, cis), 4.65 (dd, 7.8, 2.2 Hz, 1H, trans), 3.85 (s, 3H, trans), 3.21 (s, 3H, cis).

Vinyl epoxide coupling

The palladium catalyst (4 mol%), phenylboronic acid (1 eq.), and Cs2CO3 (2 eq.) were dissolved in 10:1 THF:H2O (3 cm3). The 2-vinylxirane was then added (1 eq.), and the reaction was stirred at rt for 24 h. The solvent was removed in vacuo, dissolved in DCM (5 cm3), washed with H2O (5 cm3), and separated using a hydrophobic frit. The solvent was then removed in vacuo yielding the mixture of linear and branched products. 1H NMR (500 MHz, chloroform-d) δ 7.40–7.20 (m, 10H), 6.03 (dd, J = 18.0, 10.7, 7.3 Hz, 1H, branched), 5.91–5.85 (m, 1H, linear), 5.77–5.69 (m, 1H, linear), 5.24–5.19 (m, 2H, branched), 4.13 (s, 2H, linear), 3.88–3.81 (m, 2H, branched), 3.55 (dt, 7.3, 7.3 Hz, 1H, branched), 3.40 (d, 6.7 Hz, 2H, linear), 1.66 (s, 1H, branched), 1.45 (s, 1H, linear). 13C NMR (100 MHz, chloroform-d) δ 140.7 (branched), 140.0 (linear), 138.3 (branched), 131.5 (linear), 130.3 (linear), 128.7 (branched), 128.5 (linear), 128.4 (linear), 126.9 (branched), 126.1 (linear), 117.0 (branched), 66.1 (branched), 63.5 (linear), 52.5 (branched), 38.6 (linear).
