ABSTRACT

Business model innovation has seen a recent surge in academic research and business practice. Changes to business models are recognised as a fundamental approach to realise innovations for sustainability. However little is known about the successful adoption of sustainable business models (SBMs). The purpose of this paper is to develop a unified theoretical perspective for understanding business model innovations that lead to better organizational economic, environmental and social performance. The paper examines bodies of literature on business model innovation, sustainability innovation, networks theory, stakeholder theory and product-service systems. We develop five propositions that support the creation of SBMs in a unified perspective which lays a foundation to support organizations to investigate and experiment with alternative new business models. This article contributes to the emerging field of SBMs, which embed economic, environmental and social flows of value that are created, delivered and captured in a value network. It highlights gaps for addressing the challenges of business model innovation for sustainability and suggests avenues for future research.

Keywords: business models; business model innovation; sustainability innovation; sustainable business models; sustainable value creation; business model experimentation

Introduction

Business strategy and management disciplines are increasingly incorporating sustainable development into their long-established assumptions and frameworks, stimulating rich, new and diverse fields of study (Winn and Kirchgeorg, 2005), and rethinking the theoretical foundations and the practice of business strategy (Hahn et al., 2010). Theoretical and practical approaches to sustainability have been proposed with some common properties: improving sustainability often implies change, innovation or adjustment of an entity in relation to its surroundings or supporting environment (Faber et al., 2005). The ability to innovate in the domain of sustainability represents a necessary business capability, whether related to small incremental steps or to radical, disruptive innovations (Adams et al., 2012). Business model innovation is emerging as a potential mechanism to integrate sustainability into the business (Schaltegger et al., 2012; Jolink and Niesten, 2015). However, there is a lack of clarity, conceptual consensus and consistency in the use of the terms ‘business model’, ‘business model innovation’ and ‘sustainable business models’ (Magretta, 2002; Osterwalder and Pigneur, 2005; Boons and Lüdeke-Freund, 2013), and a lack of established theoretical grounding in economics or business studies (Teece, 2010). Moreover, there is no general agreement on the characterization, classification and boundaries of these concepts (Spieth et al., 2014) which results in
dispersion of perspectives and significantly slows down and even hampers the progress in these fields (Zott et al., 2011). The lack of theoretical grounding is also reflected into the scarce number of case studies and empirical analyses in the field. There is a paucity of empirical research on business models, business model innovation and SBMs (Stubbs and Cocklin, 2008; Birkin et al., 2009; Schaltegger et al., 2012).

The lack of case studies makes it challenging for firms to understand how to innovate their business models, how to identify and design alternatives, then assess and select the most adequate one. When considering business model innovations for sustainability, this leads to a higher complexity related to how to preliminarily assess the impact of the sustainability innovations and how to understand their effects on the whole business network. The purpose of this paper is to present a unified perspective for innovation towards SBMs leading to better economic, environmental and social performance of organisations. The paper proposes a conceptual foundation as basis for experimentation and exposes the potential benefits of using simulation for the design and evaluation of business model innovation alternatives.

This paper explores several bodies of literature. We begin by examining whether and how business models can be innovated to achieve sustainability goals. Based on research in business model innovation (Teece, 2010; Amit and Zott, 2012; Spieth et al., 2014) and sustainability innovations (Hellström, 2007; Adams et al., 2012; Boons et al., 2013), we identify several concepts, which characterise SBMs. We also draw on contributions from networks (Provan et al., 2007; Allee, 2008) and stakeholder theories (Haigh and Griffiths, 2009) which underpin the concept of sustainable value flows among multiple stakeholders of the business and elicit the complexity of SBMs; and product-service systems (Evans et al., 2007; Tukker, 2015) which brings insights into specific characteristics of what is considered a promising SBM. We develop five propositions that frame the concept of SBMs. We suggest implications for organisations to experiment with business model innovations for sustainability and assess the potential impact of these innovations. We conclude with directions for future research.

Understanding Business Model Innovation for Sustainability

Commonly accepted explanations consider that business models refer to the logic of how a firm does business, and explain how the firm creates, delivers and captures value (Magretta, 2002; Teece, 2010). However, there is no general agreement on the concept of business models. De Reuver et al. (2013) even highlight differences between American and European scholars approach to business model research; the former focusing on classifications and the relation with open innovation, while the latter concentrates on causal modelling and design approaches. Lambert (2015) reveals that empirically-grounded classifications of business models are still scarce and adopt two perspectives: classification schemes with no explicit criteria; and theoretical typologies including ad-hoc criteria based on prior theories in economics, strategy and entrepreneurship.

Spieth et al. (2014) suggest that the business model concept goes far beyond simple storytelling of how a firm does business and has a potential to provide a holistic perspective of firm’s activities. Teece (2010) suggests that the design of business models enables the reconfiguration of business capabilities to adapt the firm to the changing business environment. Business models are seen as a vehicle for innovation and a necessary means for commercialising technological innovations, as well as a subject of innovation, e.g. open innovation, collaborative entrepreneurship, business model itself as a part of intellectual property (Teece, 2010; Zott et al., 2011).

In the search for greater adaptive capacity and sustainable ways of doing business, novelty, creativity and positive innovation are bound to play a crucial role (Winn et al., 2011; Hall and Wagner, 2012). Sustainability innovations not only refer to the novelty in technology, but also in processes, operating procedures and
practices, business models, systems and thinking (Szekely and Strebel, 2013). Researchers from different disciplines (economic sociology, innovation, history, technology studies) have attempted to explain business model innovation for sustainability from various perspectives. Existing studies can be structured into organizational, inter-organizational, and societal levels (Boons and Lüdeke-Freund, 2013). Sustainability innovations require more integrated thinking and the reconfiguration of several business aspects such as capabilities, stakeholder relationships, knowledge management, leadership and culture (Adams et al., 2012). Schaltegger and Wagner (2011) reflect on sustainability innovations as those envisaged to make real and substantial improvements by developing superior production processes, products and services, and by exercising large market influence and social or political influence. Stubbs and Cocklin (2008) highlight that business model innovations for sustainability tend to be ad-hoc and neither systematic nor systemic. The generation of SBMs is multidimensional and complex, hence there are few known successful cases (Hart and Milstein, 2003; Lüdeke-Freund, 2010). We summarise the main challenges found in literature in Table 1.

Table 1. Challenges for creation of SBMs

**Theoretical Foundation for Innovation towards Sustainable Business Models**

This section examines existing theories and concepts related to value, stakeholders, networks, product-service systems and sustainability. We develop five propositions which provide a theoretical foundation for innovation towards SBMs.
Value and Sustainable Business Models

The concept of ‘business model’ is widely underpinned by the concept of ‘value’ in the literature. It has been specifically related to the realisation of economic value (Chesbrough and Rosenbloom, 2002), to the delivery of customer value (Magretta, 2002), to the interlocking elements that create and deliver value (Johnson et al., 2008), and to the support of the value proposition for the customer (Teece, 2010) among others. However, the word value does not mean the same to everyone in every context (Den Ouden, 2012).

Adam Smith’s view of ‘exchange value’ has been the cornerstone of economic thought which largely prevails in today’s business practice (Ueda et al., 2009). More recent debate has introduced the terms ‘value-in-use’ (Vargo and Lusch, 2007), as manufacturers move towards more service-oriented business models with a stronger customer focus; and ‘shared value’ (Porter and Kramer, 2011), suggesting that economic value should be created in a way that also creates value for society.

Economics is not the only lens used to look at the concept of value. Psychology, sociology and ecology also offer perspectives on value (Den Ouden, 2012), bringing both objective and subjective dimensions, such as belonging, eco-footprint, and meaningful life. From a sustainability perspective, a firm’s value creation logic should consider the integration of social and environmental goals into a more holistic meaning of value (Schaltegger et al., 2011). The creation of social value in addition to economic value is seen as a main driver of social entrepreneurship (Acs et al., 2013). Environmental or eco-entrepreneurship seeks to solve environmental problems while creating economic value (Schaltegger and Wagner, 2011). Sustainable value then represents not only environmental sustainability but also social and economic value (Ueda et al., 2009). Sustainability drivers, such as footprint reduction, poverty alleviation, fair distribution, waste reduction and transparency, and their associated business strategies - understood as clean technology, sustainability vision, pollution prevention and product stewardship - can take forward the creation of sustainable value for the business (Hart and Milstein, 2003). Figure 1 illustrates a holistic view of sustainable value integrating economic, environmental and social value forms.

Figure 1. Sustainable Value

Encompassing economic, environmental and social aspects while considering the needs of all stakeholders rather than giving priority to shareholders’ expectations (Stubbs and Cocklin, 2008) and aligning the interests of all stakeholder groups (Evans et al., 2014) are seen as key aspects of SBMs. Lüdeke-Freund (2010) reflects
on business models that create superior customer value, understood as creating value for customers and contribution to the sustainable development of both the firm and society, as SBMs and organizational eco-innovations.

SBMs are not necessarily achieved through technology, products or service innovation alone, but also through the innovation of the business model itself (Girotra and Netessine, 2013; Yang et al., 2016). This implies changes in the way business models are conceptualised in regard to their exchanges and relations with stakeholders. The relationships that connect the firm to its stakeholders influence the way a firm is governed and, in turn, are influenced by the firm’s behaviour (Perrini and Tencati, 2006). Leading companies are transforming these relationships by taking wider and long-term view, which enable the move from a transactional mind-set towards the development of trust-based, mutually beneficial, and enduring relationships with key internal and external stakeholders (Gulati and Kletter, 2005). Clarkson (1995) classified stakeholders into primary, whose participation is imperative for the firm to function, such as employees, suppliers, consumers and shareholders/investors; secondary, who are not engaged in transactions with the firm and not essential for its survival, such as media; and public stakeholders who provide external support to the firm, such as governments, universities, communities, internal organizations, local and international non-governmental organizations. Edgeman and Eskildsen (2014) state that long-term enterprise success is ‘a consequence of balancing both the competing and complementary interests of key stakeholder segments, including society and the natural environment, to increase the likelihood of superior and sustainable competitive positioning’. Hence, treating society and nature as stakeholders of the firm are important elements of the conceptualisation of SBMs (Stubbs and Cocklin, 2008). The role of the natural environment as a valid primary stakeholder was finally argued by Haigh and Griffiths (2009) who demonstrate that the natural environment has an economic stake in organizations and ‘affect or is affected by’ the business.

To summarize, the scope of value should include not only economic transactions but also relationships, exchanges and interactions that take place among stakeholders (Allee, 2011) and that can be represented by value flows (Den Ouden, 2012). Identifying all the value flows among stakeholders, including the natural environment and society as primary stakeholders, can reveal opportunities for business model innovation.

Proposition 1: Sustainable value incorporates economic, social and environmental benefits conceptualised as value forms.

Proposition 2: Sustainable business models require a system of sustainable value flows among multiple stakeholders including the natural environment and society as primary stakeholders

Value Networks and Stakeholder Mutuality

Integrating sustainability into business models requires a systemic view that considers the global perspective and different elements of the system and their interrelations (Stubbs and Cocklin, 2008). Value networks analysis provides such a view and can inform changes regarding a firm’s business model (Kothandaraman and Wilson, 2001; Allee, 2011).

The term ‘network’ refers generally to a group of three or more organizations, either self-initiated or contracted, connected in ways that facilitate the achievement not only of their own goals but also of a common goal (Borgatti and Foster, 2003; Provan and Kenis, 2007). Scholars in organizational studies use different terms to refer to this phenomenon such as partnerships, strategic alliances, interorganizational relationships, coalitions, cooperative arrangements, or collaborative agreements (Gulati and Kletter, 2005; Provan et al., 2007). The overall focus of the network has been a source of differentiation between disciplines, giving the general concept several names depending on the motivation of the network, e.g.
innovation networks (Dhanaraj and Parkhe, 2006; Corsaro et al., 2012), supply networks (Harland et al., 2004; Van Bommel, 2011), and manufacturing networks (Rudberg and Olhager, 2003). Introducing the concept of value, including both tangible and intangible values, into business networks has broadened the research area and established the concept of value networks. A value network is seen as a set of roles and interactions in which organizations engage in both tangible and intangible value exchanges to achieve economic or social good (Allee, 2008). Value networks involve different roles and organizations with different needs; hence it is necessary to make specific propositions that create value for all participants in the network (Den Ouden, 2012).

Traditional network research has extensively investigated the organizations that compose the network, while the whole network as a form of governance has not been so frequently studied (Provan et al., 2007). Understanding network dynamics would influence managers decisions regarding entering into new alliances by providing information on constraints from their current ties (Gulati, 1998). Network governance is needed for goal-oriented networks if they are to be effective (Provan and Kenis, 2007). Stable networks reinforce relational ties among members and ensure equitable distribution of value (Dhanasaj and Parkhe, 2006). A new governance model is needed to realise a system in which ‘sustainability issues are integrated in a way that ensures value creation for the firm and beneficial results for all stakeholders in the long term’ (UNEP, 2014; Vermeulen, 2015).

The implementation of sustainability into networks lacks a systemic approach so far, focusing mainly on improvements of environmental aspects and limiting the social aspect to recent developments of codes of conduct, guidelines and conventions (Van Bommel, 2011). The integration of sustainability at network level (Figure 2) and the achievement of common and individual goals within the network could be then enhanced by new governance mechanisms. Rethinking the purpose of the firm as part of a value network could enable innovations towards new SBMs.

Figure 2. Sustainable Value Network

Balancing the ecological, social and economic sustainability aspects of a system requires an approach that builds on the assumption that each of the three sub-systems must be viable and healthy if the planet system is to flourish (Ehrenfeld and Hoffman, 2013). Faber et al. (2005) conceptualize sustainability in firms as ‘equilibrium between an artefact and its supporting environment, where they interact with each other without mutual detrimental effects. Sustainability explicitly refers to this equilibrium’. Achieving the equilibrium, however, is a formidable undertaking for firms and society at large. Argandoña (2011) states
that as long as the focus of the firm remains in economic value, any solution adopted will be insufficient because the process of capturing that value will be vulnerable to conflicts. If the value created in firms is of several types, however, it is possible to find better ways of creating economic and non-economic value in a sustained way, so that all stakeholders who help to create the value also share the benefits (Argandoña, 2011). Pandey and Gupta (2008) propose that socially conscious organizations are based on mutual recognition and acceptance of others, including customers and other stakeholders, as ‘responsible’ parties.

In order to realise an integrated and balanced system, deliberate interaction, partnering, networking and learning from multiple and diverse stakeholders is critical (Winn and Kirchgeorg, 2005). It is no longer a choice for firms whether to engage with stakeholders or not; the challenge is rather how to engage successfully (Jeffery, 2009). Thus, greater stakeholder engagement, alongside greater trust and innovations to their business models are among the big changes that firms need to undertake in the pursuit of a long-term aim for sustainability (Krantz, 2010; Bolton and Landells, 2015). Den Ouden (2012) suggests that specific arrangements are required for all parties in order to have a sustained portion both at the beginning and in the longer term so they contribute to the flourishing of the whole system. The analysis of the value flows within the network shows how different choices affect the mutual satisfaction of stakeholders, and hence the sustainability of the network (Shaw, 2010). Mutual value creation in SBMs, therefore, requires systemic consideration of a wide set of stakeholders who have a stake and responsibility in the value creation system.

**Proposition 3:** Sustainable business models require a value network with a new purpose, design and governance.

**Proposition 4:** Sustainable business models require a systemic consideration of stakeholder interests and responsibilities for mutual value creation.

**Product-Service Systems**

Innovation opportunities arise from considering wider system boundaries that integrate externalities like environmental impacts, the use and the end-of-life phases of products, and social implications, into the value network (Evans et al., 2009). A debate on environmental externalities, their relation to sustainability and their implications for environmental and sustainability related policies arose in the field of ecological economics (Baumgärtner and Quaas, 2010). From this viewpoint, environmental externalities are seen as unwanted side effects related to welfare losses and environmental damage (Van der Berg, 2010) that can be internalized by using conventional economic instruments, such as taxes and permits (Bithas, 2011). Maxwell and Van der Vorst (2006) suggest a similar approach, by monetizing environmental externalities, e.g. costs of products end-of-life recovery, reuse, treatment or disposal, to optimise the economic aspects as part of the criteria for sustainable product and services design.

An example of new business models which integrate additional activities and risk in the product use phase are the service-based business concepts (Lay et al., 2009). Product-Service Systems (PSS), one of those emerging business concepts, are seen as a combination of tangible products and intangible services that are jointly capable of fulfilling final customer needs (Tukker, 2015). Many authors have discussed the potential of PSS to achieve sustainability through reduction of environmental impact and fomenting sustainable production and consumption (Tukker, 2015; Vezzoli et al., 2015).

Life cycle thinking is considered an essential concept for developing sustainable PSS in a holistic way (Aurich et al., 2006; Linder and Williander, 2015). From a network perspective, supply chain management play also a key role in PSS design (Vezzoli et al., 2015). PSS contractual agreements could reflect the internalisation of some activities under the service provider responsibility during the use phase and the end-of-life phase of
products. Some characteristics of these contractual agreements regard ownership and property rights, personnel involved and customers served, payment model and end-of-life activities such as retrieval and recycling (Lay et al., 2009).

The nature of PSS - providing functionalities or outcomes to customers, as opposed to products - makes firms accountable for the economic, environmental and social issues during and after the product use phase. These externalities of product-based business models are brought into the core of the PSS concept. In order to internalize them, it is important to incorporate the concepts of life cycling thinking and to establish new modes of ownership that brings firms higher responsibilities. Developing PSS or transforming an existing business model towards PSS has been a pioneering innovation of business models for sustainability.

Proposition 5: Internalizing externalities through product-service systems enables innovation towards sustainable business models.

Implications for Organisations

This section presents two significant implications for firms considering innovation towards SBMs. Namely, how organizations can experiment with sustainable business models and how to assess the impact of business model innovations.

Experimentation with Sustainable Business Models

Business model innovation can be a large undertaking for a firm and its stakeholders, the effects cascading throughout the value network. Given the uncertainty regarding processes and outcomes of business model innovation, it is widely understood that firms are hesitant to pilot business model innovations in the real world (Thompson and MacMillan, 2010). Nevertheless, several authors suggest that experimentation, trial-and-error and learning are all methods required for discovering new business models and simultaneously obtaining a better grasp of the business model as a unit of analysis (Baden-Fuller and Morgan, 2010; McGrath 2010). These methods, however, require significant resources (e.g., financial capital) and carry substantial risks (e.g. failure).

Researchers can instil practitioners with confidence regarding business model innovation by conducting further empirical analyses and recommending ways in which companies can easily experiment with business models (Girotra and Netessine, 2013). Baden-Fuller and Morgan (2010) challenge researchers to experiment with business models as biologists and economists experiment with model organisms and mathematical models, respectively. One solution for inexpensive and low-risk experimentation is simulation (Thomke et al., 1998) which can provide researchers and practitioners with an environment for testing business models without the financial and physical resources required to test in the real world.

Being that a business model will ultimately be the mediator between various actors in a real-world value network, the simulation environment for business model innovation must reflect human behaviour and decision-making. Increasingly, researchers and practitioners are adopting and validating the use of behavioural models such as system dynamics (DuranEncalada and Paucar-Caceres, 2012; Kampmann and Sterman, 2014; Abdelkafi and Täuscher, 2015) and agent-based models (Bonabeau, 2002; Zhang and Zhang, 2007; Vanhaverbeke and Macharis, 2011) to simulate business model innovation and other business-related activities. The range of examples in the literature suggests the validity of pursuing a behavioural model, with its ability to methodically address complexity and to enable firms to experiment with SBMs, as the experimentation method of simulation involves less cost and risk.
This journey around the current literature on experimentation with business models demonstrates a gap in the knowledge regarding the drivers of successful business model innovation and the methods by which new business models can be safely pursued. Furthermore, the knowledge on experimentation with SBMs is even scarcer. Researchers therefore need to find ways to provide companies the confidence that they need to innovate towards SBMs.

**Assessing the Impact of Sustainable Business Models**

Since business model innovation is considered a value creation mechanism as elaborated in this paper, it raises the question: how do we assess the impact and the value creation potential of SBMs?

UNEP (2014) identified over two hundred academic reports which demonstrate positive and statistically significant relationships between sustainability performance and financial performance, and an increasing number of financial reports which cover sustainability issues ranging from climate change and energy efficiency to gender diversity. In response to pressures in the areas of corporate social responsibility and social and environmental accounting, more and more firms are publishing ‘triple bottom line’ and ‘sustainable development’ reports (Brown and Fraser, 2006). At the time of writing this paper, over 78,797 sustainability reports were listed on CorporateRegister.com. At the same time, the ‘triple bottom line’ perspective is exponentially increasing the scope of measurement options with emerging competing frameworks that are complex and with no indication of reaching an agreement on a common reporting standard (Hubbard, 2009; Lee et al., 2016). These multiple financial, social, and environmental measurements are often presented under the umbrella of ‘environmental, social and governance’ (ESG) metrics (Porter et al., 2012; Beckmann et al., 2014). Despite a myriad of existing ESG metrics, it is still difficult to measure the gains achieved by business model innovation, especially in the area of sustainability, where many metrics are still under development (e.g., local water stress) or not well understood (e.g., wellbeing, biodiversity).

It is becoming increasingly clear that sustainability performance measurement must extend beyond the boundaries of any one firm, and need to consider the broader issue of enterprise sustainability (Searcy, 2014). The measurement of a firm’s success, therefore, cannot be limited to the creation of value for only one stakeholder group, typically the shareholders, but rather extend to the entire set of stakeholder relationships which become strategic for the long-term success and survival of a firm (Perrini and Tencati, 2006).

We identify two fundamental issues that firms face when trying to assess the impact of SBMs. On the one side, there is a lack of a clear measurement system for the economic, environmental and social value creation potential of SBMs. On the other side, the assessment involves multiple stakeholders with different stakes, goals and value creation ability in the business model. How this assessment is performed in a meaningful manner presents a challenging task for practitioners and researchers in the field of SBMs.

**Conclusions**

This paper aims to strengthen the theoretical foundation of the emerging field of sustainable business models by presenting a unified perspective drawing on multiple bodies of literature - business model innovation, sustainability innovation, networks theory, stakeholder theory and product-service systems. This paper also contributes to the broader research area of business model innovation by unpacking the concept of value creation from a sustainability perspective. We develop five propositions (Table 2), which lay the foundation concepts for innovation towards SBMs.
Sustainable value incorporates economic, social and environmental benefits conceptualised as value forms.

SBMs require a system of sustainable value flows among multiple stakeholders including the natural environment and society as primary stakeholders.

SBMs require a value network with a new purpose, design, and governance.

SBMs require a systemic consideration of stakeholder interests and responsibilities for mutual value creation.

Internalizing externalities through product-service systems enables innovation towards SBMs.

**Table 2. Unified perspective for innovation towards SBMs**

**Implications for Research**

The study of SBMs is evolving rapidly, but little effort has been spent exploring their successful adoption. This work attempts to address this gap, identify opportunities to enhance outcomes of SBM innovations, and contribute to the development of new theory that will be of utility to the wider SBM community. Based on the discussions in this review we propose the following directions for future research. Further research might investigate the development of a set of variables from the five theoretical propositions, and the relationships among the variables to deepen the understanding of the ideas exposed in the propositions. A main source of complexity in business model innovation is given by the uncertainty of impacts and behaviours of network members regarding the three sustainability dimensions. A simulation model, therefore, should be built to support a focal firm to identify value flows and exchanges, which could reveal opportunities for business model innovations and de-risk experimentation. The simulation model should demonstrate the environmental, economic and social impact of new business models.

**Implications for Business Strategy**

Our most important recommendation to business practice is to encourage firms to understand their current business model better, embrace the concepts of SBMs, and potentially identify entirely new and more appropriate future business models. The implication for business strategy is that firms need to understand the challenges in the adoption of SBMs. Their business strategy should reflect the scale and complexity of business model innovation for sustainability and the demand to develop new business models through experimentation. Business model innovation should not be taken lightly as the impact assessment of new business models is complex and context dependent. Nevertheless, these endeavours will be of interest to industrialists seeking to meet the pressing need for sustainable development and the transition to more sustainable industrial systems to respond to growing economic, environmental, and social challenges.

**Implications for Policy**

This work also aims to increase the understanding of how policy makers can best deliver system-level sustainability outcomes concerning energy use, resource depletion, waste to land-fill, emissions, wealth creation. To achieve this, policy makers need to better understand what business model characteristics lead to real triple-bottom-line sustainability, and what operational, behavioural and policy interventions might be required to facilitate such innovations. Policy makers, and other interested stakeholders, may want to pay
special attention to the proposed challenges and propositions about when stakeholders are most likely to contribute to the successful innovation towards SBMs. Policy can have impact at the individual firm level and also at the wider industrial system level, transforming stakeholders’ behaviour accordingly through appropriate policy interventions like regulation, legislation, taxation, education, and incentives.

ACKNOWLEDGEMENTS

This study was supported by the EPSRC project ‘Business Models for Sustainable Industrial Systems’ (grant n° EP/L019914/1) and the EPSRC Centre for Innovative Manufacturing in Industrial Sustainability (grant n° EP/I033351/1).
