Measurement of the CP -violating phase ϕ_s in $B_s^0 \rightarrow J/\psi\phi$ decays in ATLAS at 13 TeV

The ATLAS Collaboration

A measurement of the $B_s^0 \rightarrow J/\psi\phi$ decay parameters using 80.5 fb^{-1} of integrated luminosity collected with the ATLAS detector from 13 TeV proton–proton collisions at the LHC is presented. The measured parameters include the CP -violating phase ϕ_s , the width difference $\Delta\Gamma_s$ between the B_s^0 meson mass eigenstates and the average decay width Γ_s . The values measured for the physical parameters are combined with those from 19.2 fb^{-1} of 7 TeV and 8 TeV data, leading to the following:

$$\begin{aligned}\phi_s &= -0.087 \pm 0.037 \text{ (stat.)} \pm 0.019 \text{ (syst.) rad} \\ \Delta\Gamma_s &= 0.0640 \pm 0.0042 \text{ (stat.)} \pm 0.0024 \text{ (syst.) ps}^{-1} \\ \Gamma_s &= 0.6698 \pm 0.0014 \text{ (stat.)} \pm 0.0015 \text{ (syst.) ps}^{-1}\end{aligned}$$

Results for ϕ_s and $\Delta\Gamma_s$ are also presented as 68% confidence level contours in the ϕ_s – $\Delta\Gamma_s$ plane. Furthermore, the transversity amplitudes and corresponding strong phases are measured. All measurements are in agreement with the Standard Model predictions.

1 Introduction

In the presence of new physics (NP) phenomena, sources of CP violation in b -hadron decays can arise in addition to those predicted by the Standard Model (SM) [1]. In the $B_s^0 \rightarrow J/\psi\phi$ decay, CP violation occurs due to interference between a direct decay and a decay with B_s^0 – \bar{B}_s^0 mixing. The oscillation frequency of B_s^0 meson mixing is characterised by the mass difference Δm_s of the heavy (B_H) and light (B_L) mass eigenstates. The CP -violating phase ϕ_s is defined as the weak phase difference between the B_s^0 – \bar{B}_s^0 mixing amplitude and the $b \rightarrow c\bar{c}s$ decay amplitude. In the SM the phase ϕ_s is small and is related to Cabibbo–Kobayashi–Maskawa (CKM) quark mixing matrix elements via the relation $\phi_s \simeq -2\beta_s$, with $\beta_s = \arg[-(V_{ts}V_{tb}^*)/(V_{cs}V_{cb}^*)]$. By combining beauty and kaon physics observables, and assuming no NP contributions to B_s^0 mixing and decays, a value of $-2\beta_s = -0.0365^{+0.0013}_{-0.0012}$ rad was predicted by the CKMFitter group [2] and $-2\beta_s = -0.037 \pm 0.002$ rad according to the UTfit Collaboration [3]. While large NP enhancements of the mixing amplitude have been excluded by the precise measurement of the oscillation frequency [4], the NP couplings involved in the mixing may still increase the size of the observed CP violation by enhancing the mixing phase ϕ_s with respect to the SM value.

Other physical quantities involved in B_s^0 – \bar{B}_s^0 mixing are the decay width $\Gamma_s = (\Gamma_L + \Gamma_H)/2$ and the width difference $\Delta\Gamma_s = \Gamma_L - \Gamma_H$, where Γ_L and Γ_H are the decay widths of the light and heavy mass eigenstates, respectively. In the SM the width difference is predicted to be $\Delta\Gamma_s = 0.087 \pm 0.021$ ps⁻¹ [5]. A potential NP enhancement of ϕ_s would also decrease the size of $\Delta\Gamma_s$, but it is not expected to be affected as significantly as ϕ_s [6]. Nevertheless, extracting $\Delta\Gamma_s$ from data is an important test of theoretical predictions [6].

The analysis of the time evolution of the $B_s^0 \rightarrow J/\psi\phi$ decay provides the most precise determination of ϕ_s and $\Delta\Gamma_s$. Previous measurements of these quantities have been reported by the D0, CDF, LHCb, ATLAS and CMS Collaborations [7–12]. Additional improvements in measuring ϕ_s from $B_s^0 \rightarrow \psi(2S)\phi$ and $B_s^0 \rightarrow D_s^+ D_s^-$ decays have been achieved by the LHCb Collaboration [13, 14].

The analysis presented here introduces a measurement of the $B_s^0 \rightarrow J/\psi\phi$ decay parameters using 80.5 fb⁻¹ of LHC proton–proton (pp) data collected by the ATLAS detector during 2015–2017 at a centre-of-mass energy, \sqrt{s} , equal to 13 TeV. The analysis closely follows a previous ATLAS measurement [10] that was performed using 19.2 fb⁻¹ of data collected at 7 TeV and 8 TeV, and introduces more-precise signal and background models.

2 ATLAS detector and Monte Carlo simulation

The ATLAS detector¹ consists of three main components: an inner detector (ID) tracking system immersed in a 2 T axial magnetic field, electromagnetic and hadronic calorimeters, and a muon spectrometer (MS). The inner tracking detector covers the pseudorapidity range $|\eta| < 2.5$, and consists of silicon pixel, silicon microstrip, and transition radiation tracking detectors. The ID is surrounded by a high-granularity liquid-argon (LAr) sampling electromagnetic calorimeter. A steel/scintillator tile calorimeter provides hadronic coverage in the central rapidity range. The endcap and forward regions are equipped with LAr calorimeters for electromagnetic and hadronic measurements. The MS surrounds the calorimeters and

¹ ATLAS uses a right-handed coordinate system with its origin at the nominal interaction point. The z -axis is along the beam pipe, the x -axis points to the centre of the LHC ring and the y -axis points upward. Cylindrical coordinates (r, ϕ) are used in the transverse plane, r being the distance from the origin and ϕ being the azimuthal angle around the beam pipe. The pseudorapidity η is defined as $\eta = -\ln[\tan(\theta/2)]$ where θ is the polar angle.

provides a system of tracking chambers and detectors for triggering. A full description can be found in Refs. [15–17].

The data were collected during periods with different instantaneous luminosity, so several triggers were used in the analysis. All triggers were based on the identification of a $J/\psi \rightarrow \mu^+ \mu^-$ decay, with transverse momentum (p_T) thresholds of either 4 GeV or 6 GeV for the muons. Data quality requirements were imposed on the data, notably on the performance of the MS, ID and calorimeter systems. The measurement uses 80.5 fb^{-1} of pp collision data. The uncertainty in the combined 2015–2017 integrated luminosity is 2.0% [18], obtained using the LUCID-2 detector [19] for the primary luminosity measurements.

To study the detector response, estimate backgrounds, and model systematic effects, 100M Monte Carlo (MC) simulated $B_s^0 \rightarrow J/\psi \phi$ events were generated using PYTHIA 8.210 [20] tuned with ATLAS data, using the A14 set of parameter values [21] together with the CTEQ6L1 set of parton distribution functions [22]. The detector response was simulated using the ATLAS simulation framework based on GEANT4 [23, 24]. In order to account for the varying number of proton–proton interactions per bunch crossing (pile-up) and trigger configurations during data-taking, the MC events were weighted to reproduce the same pile-up and trigger conditions as in data. Additionally, background samples of both the exclusive ($B_d^0 \rightarrow J/\psi K^{0*}$ and $\Lambda_b \rightarrow J/\psi p K^-$) and inclusive ($b\bar{b} \rightarrow J/\psi X$ and $pp \rightarrow J/\psi X$) decays were simulated, using the same simulation tools as in the case of the signal events. For validation studies related to flavour tagging, detailed in Section 4, events with $B^\pm \rightarrow J/\psi K^\pm$ exclusive decays were also simulated.

3 Reconstruction and candidate selection

The reconstruction and candidate selection for the decay $B_s^0 \rightarrow J/\psi(\mu^+ \mu^-)\phi(K^+ K^-)$ is described here. Events must pass the trigger selections described in Section 2. In addition, each event must contain at least one reconstructed primary vertex, formed from at least four ID tracks, and at least one pair of oppositely charged muon candidates that are reconstructed using information from the MS and the ID. The muons used in the analysis are required to meet the *Tight*² or *Low- p_T* ³ working point identification criteria. The muon track parameters are determined from the ID measurement alone, since the precision of the measured track parameters is dominated by the ID track reconstruction in the p_T range of interest for this analysis. Pairs of oppositely charged muon tracks are re-fitted to a common vertex and the pair is accepted if the quality of the fit meets the requirement $\chi^2/\text{ndof} < 10$. In order to account for varying mass resolution in different parts of the detector, the J/ψ candidates are divided into three subsets according to the pseudorapidity η of the muons. In the first subset, both muons have $|\eta| < 1.05$, where the values $\eta = \pm 1.05$ correspond to the edges of the barrel part of the MS. In the second subset, one muon has $1.05 < |\eta| < 2.5$ and the other muon $|\eta| < 1.05$. The third subset contains candidates where both muons have $1.05 < |\eta| < 2.5$. A maximum likelihood fit is used to extract the J/ψ mass and the corresponding mass resolution for these three subsets, and in each case the signal region is defined symmetrically around the fitted mass, so as to retain 99.7% of the J/ψ candidates identified in the fits.

² Tight muon reconstruction is optimised to maximise the purity of muons at the cost of some efficiency, requiring combined muons with hits in at least two stations of the MS and additional criteria, described in Ref. [25].

³ This working point is optimised to provide good muon reconstruction efficiency down to a p_T of ≈ 3 GeV, while controlling the fake-muon rate. It allows ≥ 1 (≥ 2) MDT station tracks up to $|\eta| < 1.3$ ($1.3 < |\eta| < 1.55$) for candidates reconstructed by algorithms utilising inside-out combined reconstruction [25]. Additional cuts on the number of precision stations and on variables very sensitive to the decays in flight of hadrons are also applied to suppress fake muons.

The candidates for the decay $\phi \rightarrow K^+K^-$ are reconstructed from all pairs of oppositely charged tracks, with $p_T > 1$ GeV and $|\eta| < 2.5$, that are not identified as muons nor as electrons. Candidate events for $B_s^0 \rightarrow J/\psi(\mu^+\mu^-)\phi(K^+K^-)$ decays are selected by fitting the tracks for each combination of $J/\psi \rightarrow \mu^+\mu^-$ and $\phi \rightarrow K^+K^-$ to a common vertex. The fit is also constrained by fixing the invariant mass calculated from the two muon tracks to the J/ψ mass [26]. A quadruplet of tracks is accepted for further analysis if the vertex fit has $\chi^2/\text{ndof} < 3$. For the $\phi \rightarrow K^+K^-$ candidate, the invariant mass of the track pairs (using a charged kaon mass hypothesis) must fall within the interval $1.0085 \text{ GeV} < m(K^+K^-) < 1.0305 \text{ GeV}$. The interval, chosen using MC simulation, is selected to retain 98% of true $\phi \rightarrow K^+K^-$ decays. The B_s^0 candidate with the lowest χ^2/ndof is selected in events where more than one candidate passes all selections. In total, 2 977 526 B_s^0 candidates are collected within the mass range of 5.150–5.650 GeV. This range is chosen to give enough background events in the sidebands of the mass distributions to allow a precise determination of the properties of background events. The mass window choice was varied and found to have a negligible systematic effect on the results.

The mean number of interactions per bunch crossing is 30, necessitating a choice of the best candidate for the primary vertex at which the B_s^0 meson is produced. The variable used is the three-dimensional impact parameter a_0 , which is calculated as the minimum distance between each primary vertex candidate and the line extrapolated from the reconstructed B_s^0 meson vertex in the direction of the B_s^0 momentum. The chosen primary vertex is the one with the smallest a_0 .

For each B_s^0 meson candidate the proper decay time t is estimated using:

$$t = \frac{L_{xy} m_B}{p_{TB}}$$

where p_{TB} is the reconstructed transverse momentum of the B_s^0 meson candidate and m_B denotes the mass of the B_s^0 meson, taken from Ref. [26]. The transverse decay length, L_{xy} , is the displacement in the transverse plane of the B_s^0 meson decay vertex relative to the primary vertex, projected onto the direction of the B_s^0 transverse momentum. The primary vertex position is recalculated after removing any tracks used in the B_s^0 meson candidate reconstruction to avoid biasing L_{xy} .

4 Flavour tagging

To identify, or *tag*, the flavour of a neutral B meson at the point of production, information is extracted using the decay of the other (or *opposite*) b -hadron that is produced from the pair production of b and \bar{b} quarks. This method is called opposite-side tagging (OST).

The OST algorithms each define a discriminating variable, based on charge information, which is sensitive to the flavour (i.e. b - or \bar{b} -quark) of the opposite-side b -hadron. The algorithms thus provide a probability that a signal B meson in a given event is produced in a given flavour. The calibration of the OST algorithms proceeds using data containing $B^\pm \rightarrow J/\psi K^\pm$ candidate decays, where the charge of the kaon determines the flavour of the B meson, providing a self-tagging sample of events. These OST algorithms are calibrated as a function of the discriminating variable, using yields of signal B^\pm mesons extracted from fits to the data. Once calibrated, the OST algorithms are applied to $B_s^0 \rightarrow J/\psi(\mu^+\mu^-)\phi(K^+K^-)$ candidate events to provide a probability that each candidate was produced in a B_s^0 or \bar{B}_s^0 meson state, which is used in the maximum likelihood fit (described in Section 5). This approach assumes invariance of the OST algorithm with respect to the specific signal b -hadron type (i.e. B^\pm meson or B_s^0 meson), which is tested and the difference is considered as a systematic uncertainty.

Figure 1: The invariant mass distribution for selected $B^\pm \rightarrow J/\psi K^\pm$ candidates. Data are shown as points, and the overall result of the fit is given by the blue curve. The contributions from the combinatorial background component are indicated by the red dotted line, partially reconstructed b -hadron decays by the purple shaded area, and decays of $B^\pm \rightarrow J/\psi \pi^\pm$, where the pion is misassigned as a kaon, by the green dashed line.

4.1 $B^\pm \rightarrow J/\psi K^\pm$ event selection

Candidate $B^\pm \rightarrow J/\psi K^\pm$ decays are identified in a series of steps. First, J/ψ candidates are selected from oppositely charged muon pairs forming a good vertex, as described in Section 3. Each muon is required to have $p_T > 4$ GeV and $|\eta| < 2.5$. Dimuon candidates with invariant mass $2.8 < m(\mu^+ \mu^-) < 3.4$ GeV, as determined from the re-fitted track parameters of the vertex, are retained for further analysis. To form the B^\pm candidate, an additional track is required, which is not identified as an electron or muon. The track is assigned the charged-kaon mass hypothesis and combined with the dimuon candidate using a vertex fit, performed with the mass of the dimuon pair constrained to the J/ψ mass. Prompt background contributions are suppressed by a requirement on the proper decay time of the B^\pm candidate of $t > 0.2$ ps.

The tagging probabilities are determined from B^+ and B^- signal events. These signal yields are derived from fits to the invariant mass distribution, $m(J/\psi K^\pm)$, and performed in intervals of the discriminating variables. To describe the $B^\pm \rightarrow J/\psi K^\pm$ signal, two Gaussian functions with a common mean are used. An exponential function is used to describe the combinatorial background and a hyperbolic tangent function to parameterise the low-mass contribution from incorrectly or partially reconstructed b -hadron decays. A Gaussian function is used to describe the $B^\pm \rightarrow J/\psi \pi^\pm$ contribution, with fixed parameters taken from simulation except for the normalisation, which is a free parameter. A fit to the overall mass distribution is used to define the shapes of signal and backgrounds. Subsequent fits are performed in the intervals of the tagging discriminating variables, separately for B^+ and B^- candidate events, with the normalisations and also the slope of the exponential function left free. The B^+ and B^- signal yields are extracted from these fits. Figure 1 shows the invariant mass distribution of B^\pm candidates overlaid with a fit to all selected candidates, and including the individual fit components for the signal and backgrounds.

4.2 Flavour tagging methods

The flavour of the signal B meson at the point of production is inferred using several methods, which differ in their efficiency and discrimination power. The measured charge of a lepton (electron or muon) from the semileptonic decay of a B meson provides strong discrimination; however, the $b \rightarrow \ell$ transitions are diluted through processes that can change the charge of the observed lepton, such as through neutral B meson oscillations, or through cascade decays $b \rightarrow c \rightarrow \ell$. The separation power of lepton tagging is enhanced by considering a weighted sum of the charge of the tracks in a cone around the lepton. If no lepton is present, a weighted sum of the charge of the tracks in a jet associated with the opposite-side b -hadron decay is used to provide discrimination. This weighted sum, or *cone charge*, is defined as:

$$Q_x = \frac{\sum_i^{N \text{ tracks}} q_i \cdot (p_{Ti})^\kappa}{\sum_i^{N \text{ tracks}} (p_{Ti})^\kappa}, \quad (1)$$

where $x = \{\mu, e, \text{jet}\}$ refers to muon, electron, or jet charge, respectively, and the summation is made using the charge of the track, q_i , and its p_{Ti} , over a selected set of tracks – including the lepton – in a cone of size $\Delta R = \sqrt{(\Delta\phi)^2 + (\Delta\eta)^2}$, around the lepton or jet direction. The value of the parameter κ – determined by the optimisation procedure – and the requirements on the tracks and ΔR are described below, dependent on the OST method.

Two subcategories of Q_x are considered: the first *discrete* category is used in the case where the cone charge is formed either from only one track or from more than one track of the same charge; this results in a cone charge of $Q_x = \pm 1$. The second *continuous* category is used when more than one track is considered, and the sum contains tracks of both negative and positive charge. In the continuous case, Q_x is divided into intervals within the range $-1 < Q_x < 1$ for each OST algorithm.

A probability $P(B|Q_x)$ is constructed, which is defined as the probability that a B meson is produced in a state containing a \bar{b} -quark, given the value of the cone charge Q_x . Since Q_x is evaluated on the opposite side, a large, negative value of Q_x tends to correspond to a higher value of $P(B|Q_x)$. An equivalent probability for the b -quark case is defined as $P(\bar{B}|Q_x)$. Using the B^\pm calibration samples, $P(Q_x|B^\pm)$ for each tagging method used can be defined. The probability to tag a B_s^0 meson as containing a \bar{b} -quark is therefore given as $P(B|Q_x) = P(Q_x|B^+) / (P(Q_x|B^+) + P(Q_x|B^-))$, and correspondingly $P(\bar{B}|Q_x) = 1 - P(B|Q_x)$. If there is no OST information available for a given B_s^0 meson, a probability of 0.5 is assigned to that candidate.

Muon tagging

For muon-based tagging, at least one additional muon is required in the event, with $p_T > 2.5$ GeV, $|\eta| < 2.5$ and with $|\Delta z| < 5$ mm, where $|\Delta z|$ is the difference in z between the primary vertex and the longitudinal impact parameter of the ID track associated with the muon. Muons are classified and kept if their identification quality selection working point is either Tight or Low- p_T ; these categories are subsequently treated as distinct flavour tagging methods. For muons with $p_T > 4$ GeV, Tight muons are the dominant category, with the Low- p_T requirement typically identifying muons of $p_T < 4$ GeV. In the case of multiple muons satisfying selection criteria in one event, Tight muons are chosen over Low- p_T muons. Within the same muon category, the muon with the highest p_T that passes the selections is used.

A muon cone charge variable, Q_μ , is constructed according to Eq. (1), with $\kappa = 1.1$ and the sum over the reconstructed ID tracks within a cone of size $\Delta R = 0.5$ around the muon direction. These tracks must have $p_T > 0.5$ GeV, $|\eta| < 2.5$, and $|\Delta z| < 5$ mm. Tracks associated with the decay of a B meson signal

candidate are excluded from the sum. In each interval of Q_μ , a fit to the $J/\psi K^\pm$ invariant mass spectrum is performed and the number of signal events extracted. The fit model used is described in Section 4.1. Figure 2 shows the distributions of the muon cone charge using B^\pm signal candidates for Tight muons, and includes the tagging probability as a function of the cone charge variable. The corresponding distributions for Low- p_T muons are shown in Figure 3.

Figure 2: Cone charge distributions, $-Q_\mu$, for Tight muons, shown for cases of discrete charge (left), and for the continuous distribution (right). For each plot, in red (blue), the normalised B^+ (B^-) cone charge distribution is shown (corresponding to the right axis scale). A B^+ (B^-) candidate is more likely to have a large negative (positive) value of Q_μ . Superimposed is the distribution of the tagging probability, $P(B|Q_\mu)$, as a function of the cone charge, derived from a data sample of $B^\pm \rightarrow J/\psi K^\pm$ decays, and defined as the probability to have a B^+ meson (on the signal-side) given a particular cone charge Q_μ . The fitted parameterisation, shown in black, is used as the calibration curve to infer the probability to have a B_s^0 or \bar{B}_s^0 meson at production in the decays to $J/\psi \phi$.

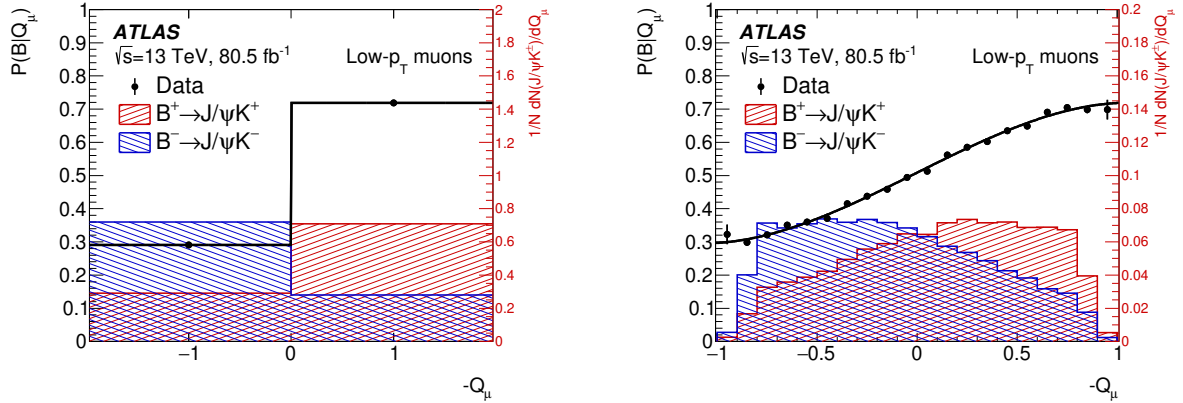

Figure 3: Normalised cone charge distributions (shown against the right axis scale), $-Q_\mu$, for B^+ (B^-) events shown in red (blue) for Low- p_T muons, for cases of discrete charge (left), and for the continuous distribution (right). Superimposed is the distribution of the tagging probability, $P(B|Q_\mu)$.

Electron tagging

Electrons are identified using ID and calorimeter information, and must satisfy the *Medium* electron quality criteria [27]. The ID track associated with the electron is required to have $p_T > 0.5$ GeV, $|\eta| < 2.5$, and $|\Delta z| < 5$ mm. To reject electrons from the signal-side of the decay, electrons with $\cos(\zeta_b) > 0.93$, where ζ_b is the opening angle between the momentum of the signal B meson candidate and the electron momentum, are not considered. In the case of more than one electron passing the selection, the electron with the highest p_T is chosen. Charged-particle tracks within a cone of size $\Delta R = 0.5$ are used to form the electron cone charge Q_e , constructed according to Eq. (1), with $\kappa = 1.0$. The resulting electron cone charge distributions are shown in Figure 4, together with the corresponding tagging probability.

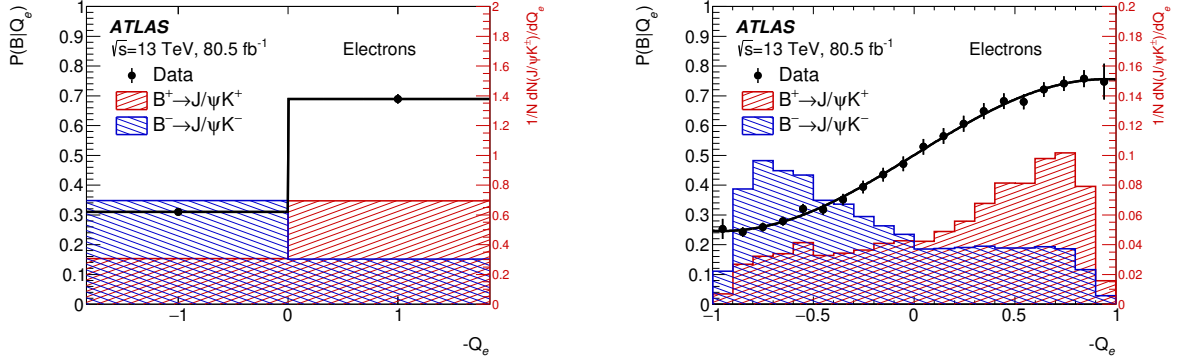

Figure 4: Normalised cone charge distributions (shown against the right axis scale), $-Q_e$, for B^+ (B^-) events shown in red (blue) for electrons, for cases of discrete charge (left), and the continuous distribution (right). Superimposed is the distribution of the tagging probabilities, $P(B|Q_e)$.

Jet tagging

In the absence of a muon or electron, a jet identified as containing a b -hadron is required. Jets are reconstructed from calorimetric information [28] using the anti- k_t algorithm [29, 30] with a radius parameter $R = 0.4$. The identification of a b -tagged jet uses a multivariate algorithm *MV2c10* [31], utilising boosted decision trees (BDT), which output a classifier value. Jets are selected if this value exceeds 0.56. This value is chosen to maximise the tagging power of the calibration sample. In the case of multiple selected jets, the jet with the highest value of the BDT output classifier is used. Jets associated with the signal decay are not considered in this selection.

Tracks within a cone of size $\Delta R = 0.5$ around the jet axis are used to define a jet cone charge, Q_{jet} , constructed according to Eq. (1), where $\kappa = 1.1$ and the sum is over the tracks associated with the jet, with $|\Delta z| < 5$ mm, and excluding tracks from the decay of the signal B meson candidate. Figure 5 shows the distribution of the opposite-side jet cone charge for B^\pm signal candidates.

4.3 Flavour tagging performance

In order to quantify and compare the performance of the various tagging methods, three figure-of-merit terms are constructed, which describe: the fraction of events used by a given tagging method, the purity

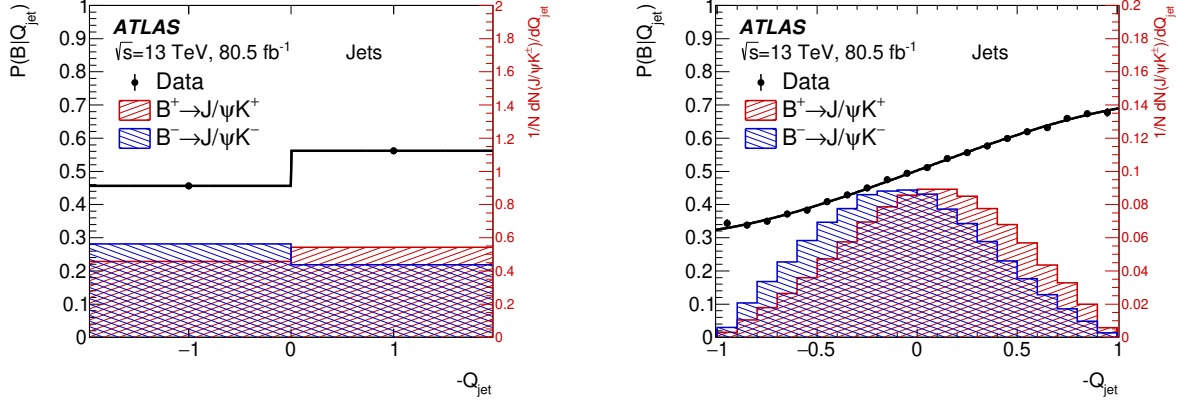

Figure 5: Normalised cone charge distributions (shown against the right axis scale), $-Q_{\text{jet}}$, for B^+ (B^-) events shown in red (blue) for jets, for cases of discrete charge (left), and the continuous distribution (right). Superimposed is the distribution of the tag probability, $P(B|Q_{\text{jet}})$.

Table 1: Summary of tagging performances for the different flavour tagging methods on the sample of B^\pm signal candidates, as described in the text. Uncertainties shown are statistical only. The efficiency (ϵ_x) and tagging power (T_x) are each determined by summing over the individual bins of the cone charge distribution. The effective dilution (D_x) is obtained from the measured efficiency and tagging power. For the efficiency, effective dilution, and tagging power, the corresponding uncertainty is determined by combining the appropriate uncertainties in the individual bins of each charge distribution.

Tag method	ϵ_x [%]	D_x [%]	T_x [%]
Tight muon	4.50 ± 0.01	43.8 ± 0.2	0.862 ± 0.009
Electron	1.57 ± 0.01	41.8 ± 0.2	0.274 ± 0.004
Low- p_T muon	3.12 ± 0.01	29.9 ± 0.2	0.278 ± 0.006
Jet	12.04 ± 0.02	16.6 ± 0.1	0.334 ± 0.006
Total	21.23 ± 0.03	28.7 ± 0.1	1.75 ± 0.01

of the method, and the overall power of the tagging method in the sample. The efficiency, ϵ_x , of an individual tagging method is defined as the number of signal events tagged by that method divided by the total number of signal events in the sample. The purity of a particular flavour tagging method, called the dilution, is defined as $\mathcal{D}(Q_x) = 2P(B|Q_x) - 1$. The tagging power of a particular tagging method is then defined as $T_x = \sum_i \epsilon_{x_i} \cdot \mathcal{D}^2(Q_{x_i})$, where the sum is over the probability distribution in intervals of the cone charge variable. An effective dilution, $D_x = \sqrt{T_x/\epsilon_x}$, is calculated from the measured tagging power and efficiency.

By definition, there is no overlap between lepton-tagged and jet-charge-tagged events. The overlap between events with a muon (either Tight or Low- p_T) and events with an electron corresponds to around 0.6% of all tagged events. In the case of multiply tagged events, the OST method is selected in order: Tight muon, electron, Low- p_T muon, jet. However, the ordering of muon- and electron-tagged events is shown to have negligible impact on the final results. A summary of the tagging performance for each method and the overall performance on the B^\pm sample is given in Table 1.

4.4 Using tag information in the B_s^0 fit

For the maximum likelihood fit performed on the B_s^0 data, and described in detail in Section 5, the per-candidate probability, $P(B|Q_x)$, that the B meson candidate was produced in a state B_s^0 (versus a \bar{B}_s^0) is provided by the calibrations derived from the $B^\pm \rightarrow J/\psi K^\pm$ sample, described above, and shown in Figures 2–5. Since the distributions of $P(B|Q_x)$ from signal B_s^0 mesons and backgrounds can be expected to be different, separate probability density functions (PDFs) are necessary to describe these distributions in the likelihood function. These PDFs are defined as $P_s(P(B|Q_x))$ and $P_b(P(B|Q_x))$, describing the probability distributions for signal and background, respectively, and are derived from the sample of B_s^0 candidates. The PDFs consist of the fraction of events that are tagged with a particular method (or are untagged), the fractions of those events categorised as discrete or continuous, and for those that are continuous, a PDF of the corresponding probability distribution.

Continuous PDF

The parameterisations of the continuous PDF components of $P_{s,b}(P(B|Q_x))$ for each OST method are defined as follows. In the sideband regions, $5.150 < m(J/\psi KK) < 5.317$ GeV and $5.417 < m(J/\psi KK) < 5.650$ GeV, unbinned maximum likelihood fits to the $P(B|Q_x)$ distributions are performed to extract the background (continuous category) PDFs for $P_b(P(B|Q_x))$. For the Tight muon and electron methods, the parameterisation has the form of the sum of a second-order polynomial and two exponential functions. A Gaussian function is used for the Low- p_T muons. For the jet tagging algorithm an eighth-order polynomial is used.

For the signal, fits are performed to the $P(B|Q_x)$ distributions, using all events in the $m(J/\psi KK)$ distributions to extract the signal (continuous category) PDFs for $P_s(P(B|Q_x))$. In these fits, the parameters describing the background PDFs are fixed to their previously extracted values, as is the relative normalisation of signal and background, extracted from a fit to the $m(J/\psi KK)$ distribution. For the signal PDFs, the Tight muon tagging method uses the sum of two exponential functions and a constant function to describe the signal. For the electron tagging method, the signal function has the form of the sum of a second-order polynomial and two exponential functions, and for the Low- p_T muon and jet tagging methods a Gaussian function is used.

Discrete PDF

In the case where the cone charge is discrete, the fractions of events f_{+1} (f_{-1}) with cone charges +1 (–1) are determined separately for signal and background using events from the signal and sideband regions of the B_s^0 mass distribution (as defined in Section 3). The remaining fraction of events, $1 - f_{+1} - f_{-1}$, corresponds to the continuous parts of the distribution. Positive and negative charges are equally probable for background candidates formed from a random combination of a J/ψ and a pair of tracks, but this is not necessarily the case for background candidates formed from a partially reconstructed b -hadron. Table 2 summarises the fractions f_{+1} and f_{-1} obtained from each tagging method for signal and background events.

The fractions of signal and background events tagged using the different OST methods are found using a similar sideband-subtraction method, and are summarised in Table 3.

Table 2: Fractions f_{+1} and f_{-1} of events with cone charges of +1 and -1, respectively, for signal and background events and for the different tagging methods. Only statistical uncertainties are given.

Tag method	Signal		Background	
	f_{+1} [%]	f_{-1} [%]	f_{+1} [%]	f_{-1} [%]
Tight muon	6.9 ± 0.3	7.5 ± 0.3	4.7 ± 0.1	4.9 ± 0.1
Electron	20 ± 1	19 ± 1	16.8 ± 0.2	17.3 ± 0.2
Low- p_T muon	10.9 ± 0.5	11.6 ± 0.5	7.0 ± 0.1	7.5 ± 0.1
Jet	3.60 ± 0.15	3.54 ± 0.15	3.05 ± 0.03	3.17 ± 0.03

Table 3: Fractions of signal and background events tagged using the different methods. The efficiencies include both the continuous and discrete contributions. Only statistical uncertainties are quoted.

Tag method	Signal efficiency [%]	Background efficiency [%]
Tight muon	4.06 ± 0.06	3.21 ± 0.01
Electron	1.86 ± 0.04	1.48 ± 0.01
Low- p_T muon	2.95 ± 0.05	2.70 ± 0.01
Jet	12.1 ± 0.1	9.41 ± 0.02
Untagged	79.1 ± 0.3	83.20 ± 0.05

To account for possible deviations of the data from the selected fit models, variations of the procedure described here are used to determine systematic uncertainties, as described in Section 6.

5 Maximum likelihood fit

An unbinned maximum likelihood fit is performed on the selected events to extract the parameter values of the $B_s^0 \rightarrow J/\psi(\mu^+\mu^-)\phi(K^+K^-)$ decay. The fit uses information about the reconstructed mass m , the measured proper decay time t , the measured mass uncertainty σ_m , the measured proper decay time uncertainty σ_t , the measured transverse momentum p_T , the tagging probability, $P(B|Q_x)$, and the transversity angles Ω of each $B_s^0 \rightarrow J/\psi\phi$ decay candidate. The measured value of the proper decay time uncertainty σ_t is calculated from the covariance matrix associated with the vertex fit for each candidate event. The transversity angles $\Omega = (\theta_T, \psi_T, \phi_T)$ are defined in Section 5.1. The likelihood function is defined as a combination of the signal and background PDFs as follows:

$$\begin{aligned}
\ln \mathcal{L} = \sum_{i=1}^N w_i \cdot \ln [& f_s \cdot \mathcal{F}_s(m_i, t_i, \sigma_{m_i}, \sigma_{t_i}, \Omega_i, P_i(B|Q_x), p_{T_i}) + f_s \cdot f_{B^0} \cdot \mathcal{F}_{B^0}(m_i, t_i, \sigma_{m_i}, \sigma_{t_i}, \Omega_i, P_i(B|Q_x), p_{T_i}) \\
& + f_s \cdot f_{\Lambda_b} \cdot \mathcal{F}_{\Lambda_b}(m_i, t_i, \sigma_{m_i}, \sigma_{t_i}, \Omega_i, P_i(B|Q_x), p_{T_i}) \\
& + (1 - f_s \cdot (1 + f_{B^0} + f_{\Lambda_b})) \mathcal{F}_{\text{bkg}}(m_i, t_i, \sigma_{m_i}, \sigma_{t_i}, \Omega_i, P_i(B|Q_x), p_{T_i})],
\end{aligned} \tag{2}$$

where N is the number of selected candidates, w_i is a weighting factor to account for the trigger efficiency (described in Section 5.3). The terms \mathcal{F}_s , \mathcal{F}_{B^0} , \mathcal{F}_{Λ_b} and \mathcal{F}_{bkg} are the PDFs modelling the signal, B^0

background, Λ_b background, and the other background distributions, respectively. The term f_s is the fraction of signal candidates and f_{B^0} and f_{Λ_b} are the background fractions of B^0 mesons and Λ_b baryons misidentified as B_s^0 candidates, calculated relative to the number of signal events. These background fractions are fixed to their expectation from the MC simulation, and variations are applied as part of the evaluation of the effects of systematic uncertainties. The mass m_i , the proper decay time t_i and the decay angles Ω_i are the values measured from the data for each event i . A detailed description of the signal PDF terms in Eq. (2) is given in Section 5.1. The three background functions are described in Section 5.2.

5.1 Signal PDF

The PDF used to describe the signal events, \mathcal{F}_s , has the following composition:

$$\begin{aligned} \mathcal{F}_s(m_i, t_i, \sigma_{m_i}, \sigma_{t_i}, \Omega_i, P_i(B|Q_x), p_{T_i}) &= P_s(m_i|\sigma_{m_i}) \cdot P_s(\sigma_{m_i}|p_{T_i}) \cdot P_s(t_i, \Omega_i|\sigma_{t_i}, P_i(B|Q_x)) \\ &\cdot P_s(\sigma_{t_i}|p_{T_i}) \cdot P_s(P_i(B|Q_x)) \cdot A(\Omega_i, p_{T_i}) \cdot P_s(p_{T_i}). \end{aligned}$$

The mass term $P_s(m_i|\sigma_{m_i})$ is modelled in the following way:

$$P_s(m_i|\sigma_{m_i}) \equiv \frac{1}{\sqrt{2\pi}S_m\sigma_{m_i}} \cdot e^{\frac{-(m_i-m_{B_s})^2}{2(S_m\sigma_{m_i})^2}}. \quad (3)$$

The term $P_s(m_i|\sigma_{m_i})$ uses per-candidate mass errors, σ_{m_i} , calculated for each $J/\psi\phi$ candidate from the covariance matrix associated with the four-track vertex fit. Each measured candidate mass is convolved with a Gaussian function with a width equal to σ_{m_i} multiplied by a scale factor S_m , introduced to account for any mismeasurements. Both S_m and the mean value m_{B_s} , which is the B_s^0 meson mass, are free parameters determined in the fit.

The probability terms $P_s(\sigma_{m_i}|p_{T_i})$, $P_s(\sigma_{t_i}|p_{T_i})$ and $P_s(p_{T_i})$ are introduced to account for differences between signal and background events for the values of the per-candidate mass error, time error and p_{T_i} values, respectively. Distributions of these variables for signal and background are described by gamma functions and the method is unchanged from the analysis explained in Ref. [32]. The tagging probability term for signal $P_s(P_i(B|Q_x))$ is described in Section 4.4.

The term $P_s(t_i, \Omega_i|\sigma_{t_i}, P_i(B|Q_x))$ is a joint PDF for the decay time t and the transversity angles Ω for the $B_s^0 \rightarrow J/\psi(\mu^+\mu^-)\phi(K^+K^-)$ decay. Ignoring detector effects, the distribution for the time t and the angles Ω is given by the differential decay rate [33]:

$$\frac{d^4\Gamma}{dt d\Omega} = \sum_{k=1}^{10} \mathcal{O}^{(k)}(t) g^{(k)}(\theta_T, \psi_T, \phi_T),$$

where $\mathcal{O}^{(k)}(t)$ are the time-dependent functions corresponding to the contributions of the four different amplitudes (A_0 , A_{\parallel} , A_{\perp} , and A_S) and their interference terms, and $g^{(k)}(\theta_T, \psi_T, \phi_T)$ are the angular functions. Table 4 shows the time-dependent and the angular functions of the transversity angles. The formulae for the time-dependent functions have the same structure for B_s^0 and \bar{B}_s^0 but with a sign reversal in the terms containing Δm_s , which is a fixed parameter of the fit (using Ref. [26]). The formalism used throughout this analysis assumes no direct CP violation. In Table 4, the parameter $A_{\perp}(t)$ is the time-dependent amplitude for the CP -odd final-state configuration while $A_0(t)$ and $A_{\parallel}(t)$ correspond to CP -even final-state configurations. The amplitude $A_S(t)$ gives the contribution from the CP -odd non-resonant $B_s^0 \rightarrow J/\psi K^+ K^-$ S -wave state

(which includes the f_0 meson). The corresponding functions are given in the last four lines of Table 4 ($k = 7-10$). The amplitudes are parameterised by $|A_i|e^{i\delta_i}$, where $i = \{0, ||, \perp, S\}$, with $\delta_0 = 0$ and are normalised such that $|A_0(0)|^2 + |A_\perp(0)|^2 + |A_{||}(0)|^2 = 1$. The amplitude $|A_\perp(0)|$ is determined according to this condition, while the remaining three amplitudes are parameters of the fit. The phase δ_S is the phase difference between $A_S(0)$ and $A_0(0)$ at the resonance peak. The value $|A_S|^2$ gives the ratio of non-resonant yield to resonant yield in the interval of $m(K^+K^-)$ used in the analysis. In the sum over the mass interval, the interference terms (lines 8–10 in Table 4) are corrected by a factor $\alpha = 0.51 \pm 0.02$ that takes into account the mass-dependent differences in absolute amplitude and phase between the resonant and the S -wave amplitudes. The correction is based on the Breit–Wigner description of the resonance and on the assumption of uniform A_S . The uncertainty in the value of α has been calculated using the Flatté parameterisation [34] and the corresponding systematic uncertainty is explained in Section 6.

The angles $(\theta_T, \psi_T, \phi_T)$, are defined in the rest frames of the final-state particles. The x -axis is determined by the direction of the ϕ meson in the J/ψ rest frame, and the K^+K^- system defines the x - y plane, where $p_y(K^+) > 0$. The three angles are defined as:

- θ_T , the angle between $\vec{p}(\mu^+)$ and the normal to the x - y plane, in the J/ψ meson rest frame,
- ϕ_T , the angle between the x -axis and $\vec{p}_{xy}(\mu^+)$, the projection of the μ^+ momentum in the x - y plane, in the J/ψ meson rest frame,
- ψ_T , the angle between $\vec{p}(K^+)$ and $-\vec{p}(J/\psi)$ in the ϕ meson rest frame.

The PDF term $P_s(t_i, \Omega_i | \sigma_{t_i}, P_i(B|Q_x))$ takes into account the lifetime resolution, so each time element in Table 4 is convolved with a Gaussian function. This convolution is performed numerically on an event-by-event basis where the width of the Gaussian function is the proper decay time uncertainty, measured for each event, multiplied by a scale factor to account for any mismeasurements. The average value of this uncertainty for signal events is 69 fs.

The angular acceptance of the detector and the kinematic cuts on the angular distributions are included in the likelihood function through $A(\Omega_i, p_{T_i})$. This is calculated using a four-dimensional binned acceptance method, applying an event-by-event efficiency according to the transversity angles $(\theta_T, \psi_T, \phi_T)$ and the p_T of the candidate. The p_T binning is necessary, because the angular acceptance is influenced by the p_T of the B_s^0 candidate. The acceptance is calculated from the $B_s^0 \rightarrow J/\psi\phi$ MC events with additional weighting for p_T and η distributions. In the likelihood function, the acceptance is treated as an angular acceptance PDF, which is multiplied with the time- and angle-dependent PDF describing the $B_s^0 \rightarrow J/\psi(\mu^+\mu^-)\phi(K^+K^-)$ decays. As both the acceptance and time- and angle-dependent decay PDFs depend on the transversity angles they must be normalised together. This normalisation is done numerically during the likelihood fit. The PDF is normalised over the entire B_s^0 mass range, 5.150–5.650 GeV.

5.2 Background PDF

The background PDF has the following composition:

$$\begin{aligned} \mathcal{F}_{\text{bkg}}(m_i, t_i, \sigma_{t_i}, \Omega_i, P_i(B|Q_x), p_{T_i}) &= P_b(m_i) \cdot P_b(t_i | \sigma_{t_i}) \cdot P_b(P_i(B|Q_x)) \\ &\cdot P_b(\Omega_i) \cdot P_b(\sigma_{m_i} | p_{T_i}) \cdot P_b(\sigma_{t_i} | p_{T_i}) \cdot P_b(p_{T_i}). \end{aligned}$$

The proper decay time function $P_b(t_i | \sigma_{t_i})$ is parameterised as a prompt peak modelled by a Gaussian distribution, two positive-time exponential functions and a negative-time exponential function. These

Table 4: The ten time-dependent functions, $\mathcal{O}^{(k)}(t)$ and the functions of the transversity angles $g^{(k)}(\theta_T, \psi_T, \phi_T)$. The amplitudes $|A_0(0)|^2$ and $|A_{\parallel}(0)|^2$ are for the CP -even components of the $B_s^0 \rightarrow J/\psi\phi$ decay, $|A_{\perp}(0)|^2$ is the CP -odd amplitude; they have corresponding strong phases $\delta_0, \delta_{\parallel}$ and δ_{\perp} . By convention, δ_0 is set to be zero. The S -wave amplitude $|A_S(0)|^2$ gives the fraction of $B_s^0 \rightarrow J/\psi K^+ K^- (f_0)$ and has a related strong phase δ_S . The factor α is described in the text of Section 5.1. The \pm and \mp terms denote two cases: the upper sign describes the decay of a meson that was initially a B_s^0 meson, while the lower sign describes the decays of a meson that was initially \bar{B}_s^0 .

functions are convolved with the same resolution function as the signal decay time-dependence. The prompt peak models the combinatorial background events, which are expected to have reconstructed lifetimes distributed around zero. The two positive-time exponential functions represent a fraction of longer-lived backgrounds with non-prompt J/ψ , combined with hadrons from the primary vertex or from a B/D meson in the same event. The negative-time exponential function takes into account events with poor vertex resolution. The probability terms $P_b(\sigma_{m_i}|p_{T_i})$, $P_b(\sigma_{t_i}|p_{T_i})$ and $P_b(p_{T_i})$ are described by gamma functions. They are unchanged from the analysis described in Ref. [32] and explained in detail there. The tagging probability term for background events $P_b(P_i(B|Q_x))$ is described in Section 4.4.

The shape of the background angular distribution, $P_b(\Omega_i)$ arises primarily from detector and kinematic acceptance effects. The best description is achieved by Legendre polynomial functions:

$$\begin{aligned}
Y_l^m(\theta_T) &= \sqrt{(2l+1)/(4\pi)}\sqrt{(l-m)!/(l+m)!} P_l^{|m|}(\cos\theta_T) \\
P_k(x) &= \frac{1}{2^k k!} \frac{d^k}{dx^k}(x^2-1)^k \\
P_l^{|m|}(x) &= (-1)^{|m|}(1-x^2)^{|m|/2} \frac{d^{|m|}}{dx^{|m|}}(P_l(x)) \\
P_b(\theta_T, \psi_T, \phi_T) &= \sum_{k=0}^{14} \sum_{l=0}^{14} \sum_{m=-l}^l \begin{cases} a_{k,l,m} \sqrt{2} Y_l^m(\theta_T) \cos(m\phi_T) P_k(\cos\psi_T) & \text{where } m > 0 \\ a_{k,l,m} \sqrt{2} Y_l^{-m}(\theta_T) \sin(m\phi_T) P_k(\cos\psi_T) & \text{where } m < 0 \\ a_{k,l,m} \sqrt{2} Y_l^0(\theta_T) P_k(\cos\psi_T) & \text{where } m = 0 \end{cases}
\end{aligned}$$

where the coefficients $a_{k,l,m}$ are adjusted to give the best fit to the angular distributions for events in the sidebands of the B_s^0 mass distribution. These parameters are then fixed in the main fit, defined by Eq. (2). The B_s^0 mass interval used for the background fit is between 5.150 and 5.650 GeV excluding the signal mass region $|m(B_s^0) - 5.366| < 0.110$ GeV. Higher-order Legendre polynomial functions were tested as a systematic check, described in Section 6.

The background mass model, $P_b(m_i)$ is an exponential function with a constant term added.

Contamination from $B_d \rightarrow J/\psi K^{0*}$ and $\Lambda_b \rightarrow J/\psi p K^-$ events misreconstructed as $B_s^0 \rightarrow J/\psi \phi$ is accounted for in the fit through the \mathcal{F}_{B^0} and \mathcal{F}_{Λ_b} terms in the PDF described in Eq. (2). The PDFs are determined using MC simulation of these decays. The fractions of these contributions, $f_{B^0} = (4.3 \pm 0.5)\%$ and $f_{\Lambda_b} = (2.1 \pm 0.6)\%$, are defined relative to the number of the $B_s^0 \rightarrow J/\psi \phi$ signal events and are evaluated from MC simulation using production cross sections and branching fractions from Refs. [26, 35–39]. MC simulated events are also used to determine the shape of the mass and transversity angle distributions. The 3D angular distributions of $B_d^0 \rightarrow J/\psi K^{0*}$ and of the conjugate decay are modelled using input from Ref. [40], while angular distributions for $\Lambda_b \rightarrow J/\psi p K^-$ and the conjugate decay are considered flat. These distributions are sculpted for detector acceptance effects and then described by Legendre polynomial functions, Eq. (4). These shapes are used as templates in the fit. The B_d and Λ_b lifetimes are accounted for in the fit by adding additional exponential terms, scaled by the ratio of B_d/B_s^0 or Λ_b/B_s^0 masses as appropriate, where the lifetimes and masses are taken from Ref. [26]. Systematic uncertainties due to the background from $B_d \rightarrow J/\psi K^{0*}$ and $\Lambda_b \rightarrow J/\psi p K^-$ decays are described in Section 6. The contribution of the S -wave $B_d \rightarrow J/\psi K \pi$ decays as well as their interference with the P -wave $B_d \rightarrow J/\psi K^{0*}$ decays are included in the PDF of the fit, using the parameters measured in Ref. [40].

5.3 Proper decay time dependence of muon trigger efficiency

Trigger muons with high values of transverse impact parameter are especially affected by the limited tracking acceptance; this results in inefficiency at large values of the proper decay time. This inefficiency is estimated using MC simulated events, by comparing the B_s^0 proper decay time distribution obtained before and after applying the trigger selection. To account for this inefficiency in the fit, the events are reweighted by a factor w , inversely proportional to the trigger efficiency:

$$1/w = p_0 \cdot [1 - p_1 \cdot (\text{Erf}((t - p_3)/p_2) + 1)], \quad (4)$$

where Erf denotes the error function and p_0, p_1, p_2 and p_3 are parameters determined in the fit to MC events. For more than 99% of the B_s^0 candidates the inefficiency is below 2%. For the most affected candidates the inefficiency reaches up to 50% at high decay time. No significant bias or inefficiency due to offline track reconstruction, vertex reconstruction, or track quality selection criteria is observed.

5.4 Summary of the fit parameters

The joint PDF of proper decay time and decay angles includes the main physics parameters of interest:

- the CP -violating phase ϕ_s ,
- the average decay width Γ_s and the decay width difference $\Delta\Gamma_s$,
- the size of the CP -state amplitudes at $t = 0$: $|A_{\parallel}(0)|^2$, $|A_0(0)|^2$ and their corresponding strong phases δ_{\perp} and δ_{\parallel}
- and the size of the S-wave amplitude at $t = 0$: $|A_S(0)|^2$ and corresponding strong phase δ_S .

The size of the remaining amplitude $|A_{\perp}(0)|^2$ is constrained by the normalisation condition, phase δ_0 is set to zero and Δm_s is fixed as mentioned above.

The likelihood function also includes other parameters referred to as “nuisance parameters” such as: the B_s^0 signal fraction f_s , parameters describing the invariant mass and decay time-angular distributions of combinatorial background events and scale factors of mass and decay time uncertainties. In addition, there are also other nuisance parameters describing: acceptance functions, parametrisations of the angles of dedicated backgrounds $B_d \rightarrow J/\psi K^{0*}$ and $\Lambda_b \rightarrow J/\psi p K^-$ and their fractions f_{B^0} and f_{Λ_b} , the probability density functions of time error distributions $P(\sigma_{t_i} | p_{T_i})$, mass error distributions $P(\sigma_{m_i} | p_{T_i})$, p_T distributions $P(p_{T_i})$ and tagging parameters and calibrations. These parameter values are mainly fixed in the fit to the values extracted from the B_s^0 mass signal and sideband regions or from MC simulations.

6 Systematic uncertainties

Systematic uncertainties are evaluated for effects that are described below.

- **Flavour tagging:** The effects on the main physics parameters from the fit, due to uncertainties introduced by the flavour tagging procedure are assessed as follows. The statistical uncertainty due to the size of the sample of $B^\pm \rightarrow J/\psi K^\pm$ decays is included in the overall statistical uncertainty. The systematic uncertainty arising from the precision of the OST calibration, described in Section 4.2, is estimated by changing the models used to parameterise the probability distribution, $P(B|Q_x)$, as a function of the cone charge from the function used by default (a third-order polynomial for muons and a sinusoid for electrons) to one of several alternative functions: a linear function; a fifth-order polynomial; or two third-order polynomials that describe the positive and negative regions and have common constant and linear terms, but independent quadratic and cubic terms. The B_s^0 fit is repeated using the alternative models and the largest deviation from the nominal fit is assigned as the systematic uncertainty. To validate the calibration procedure, calibration curves are derived from simulated samples of B^\pm and B_s^0 signals. The variations between the curves from these two samples are propagated to the calibration curves derived from data. The differences in the parameter values between the nominal fit and that with the varied calibration curves are included in the systematic uncertainty.

An additional systematic uncertainty is assigned to account for potential dependencies on the pile-up distribution. The calibration data are split into subsets of approximately equal size, separated according to the estimated pile-up of the event, and separate calibrations are made for each subset. For the B_s^0 fit, the fit is repeated using the calibrations corresponding to the estimated pile-up of that event. Differences between the nominal and the modified fit for the parameters of interest are taken as the systematic uncertainty. For the terms $P_b(P(B|Q_x))$ and $P_s(P(B|Q_x))$, variations of the parameterisation are considered (including using histograms in place of a parameterisation). The resulting changes in the parameter values of the B_s^0 fit are similarly included in the systematic uncertainties.

- **Angular acceptance method:** The angular acceptance of the detector and the kinematic cuts, $A(\Omega_i, p_{T_i})$, described in Section 5.1, is calculated from a binned fit to MC simulated data. In order to estimate the systematic uncertainty introduced by the choice of binning, different acceptance functions are calculated using different bin widths and central values.
- **ID alignment:** The changes of the fit parameters due to residual misalignments of the ID were studied and the observed deviations are included in the systematic uncertainties.
- **Trigger efficiency:** To correct for the proper decay time dependence of trigger inefficiencies, the events are reweighted according to Eq. (4). An alternative fit is performed using different sets of binning in the MC sample used to determine the efficiency. The systematic effects are found to be negligible.
- **Best candidate selection:** The systematic uncertainty of the B_s^0 fit from the selection of the candidate with the best quality in the $\approx 5\%$ of events that are found to contain multiple candidates after cuts is estimated. In the default fit, the B_s^0 candidate with the lowest χ^2/ndof is selected. An equivalent sample is created where the candidate with the highest p_T is selected instead. Deviations from the default fit are included in the systematic uncertainties of the measurement.
- **Background angles model:** The shape of the background angular distribution, $P_b(\theta_T, \varphi_T, \psi_T)$, is described by the fourteenth-order Legendre polynomial functions, given in Eq. (4). Alternatively, higher-order Legendre polynomial functions were tested, and the changes in the fit parameter values relative to the default fit are taken as systematic uncertainties.

The shapes are primarily determined by detector and kinematic acceptance effects and are sensitive to the p_T of the B_s^0 meson candidate. For this reason, the parameterisation using the Legendre polynomial functions is performed in six p_T intervals: 10–15 GeV, 15–20 GeV, 20–25 GeV, 25–30 GeV, 30–35 GeV and >35 GeV.

The systematic uncertainties due to the choice of p_T intervals are estimated by repeating the fit, with these intervals enlarged and reduced by 1 GeV and by 2 GeV. The largest changes in the fit results are taken to represent the systematic uncertainties.

The parameters of the Legendre polynomial functions given in Eq. (4) are adjusted to give the best fit to the angular distributions for events in the B_s^0 mass sidebands. To test the sensitivity of the fit results to the choice of sideband regions, the fit is repeated with alternative choices for the excluded signal mass regions: $|(m(B_s^0) - 5.366 \text{ GeV})| > 0.085 \text{ GeV}$ and $|(m(B_s^0) - 5.366 \text{ GeV})| > 0.160 \text{ GeV}$ (instead of the default $|(m(B_s^0) - 5.366 \text{ GeV})| > 0.110 \text{ GeV}$). The changes in the fit results are assigned as systematic uncertainties.

- **B_d contribution:** The contamination from $B_d \rightarrow J/\psi K^{0*}$ events misreconstructed as $B_s^0 \rightarrow J/\psi \phi$ is accounted for in the final fit. Studies are performed to evaluate the effect of the uncertainties in the $B_d \rightarrow J/\psi K^{0*}$ fraction and the shapes of the distributions of the mass, transversity angles, and lifetime. In the MC events the angular distribution of the $B_d \rightarrow J/\psi K^{0*}$ decay is modelled using parameters taken from Ref. [40]. The contribution of the S -wave $B_d \rightarrow J/\psi K\pi$ decays as well as its interference with the P -wave $B_d \rightarrow J/\psi K^{0*}$ decays are also included in the PDF of the fit, following the parameters measured in Ref. [40]. The uncertainties of these parameters are taken into account in the estimation of the systematic uncertainty. After applying the B_s^0 signal selection cuts, the angular distributions are fitted using Legendre polynomial functions. The uncertainties of this fit are included in the systematic uncertainty.
- **Λ_b contribution:** The contamination from $\Lambda_b \rightarrow J/\psi p K^-$ events misreconstructed as $B_s^0 \rightarrow J/\psi \phi$ is accounted for in the final fit. Studies are performed to evaluate the effect of the uncertainties in the $\Lambda_b \rightarrow J/\psi p K^-$ fraction f_{Λ_b} , and the shapes of the distributions of the mass, transversity angles, and lifetime. Additional studies are performed to determine the effect of the uncertainties in the $\Lambda_b \rightarrow J/\psi \Lambda^*$ branching ratios used to reweight the generated MC sample.
- **Fit model mass and lifetime:** To estimate the systematic uncertainties due to the signal B_s^0 mass model, the default model was altered by adding a second Gaussian function in Eq. (3), which has the same structure as the first Gaussian function but a different scale factor, S_m^1 , which is an additional free parameter of the fit. The resulting changes to other fit parameter values are found to be negligible.

To test the sensitivity of the part of the fit model describing the lifetime, two systematic tests are performed. The determination of signal and background lifetime errors is sensitive to the choice of p_T bins, in which the relative contributions of these two components are evaluated. To estimate the systematic uncertainty, the fit is repeated varying the intervals of the default p_T binning. The determination of signal and background lifetime errors is also sensitive to the determination of the signal fraction. The fit is repeated by varying this fraction within one standard deviation of its uncertainty and differences are included in the systematic uncertainty.

- **Fit model S -wave phase:** As explained in Section 5.1, the model for the interference between the $B_s^0 \rightarrow J/\psi \phi(K^+ K^-)$ and the S -wave $B_s^0 \rightarrow J/\psi K^+ K^-$ is corrected by a factor $\alpha = 0.51 \pm 0.02$ to account for the mass-dependent differences in absolute amplitude and phase between the resonant

and S -wave amplitudes. To account for uncertainty in α , the fit was repeated with $\alpha = 0.51 + 0.02$ and $\alpha = 0.51 - 0.02$ values. The variations of the parameter values relative to those from the default fit using the central value $\alpha = 0.51$ are included in the systematic uncertainties.

- **Fit bias:** Due to its complexity, the fit model can be sensitive to some nuisance parameters. This limited sensitivity could potentially lead to a bias in the measured physics parameters, even when the model describes well the fitted data. To test the stability of the results obtained from the chosen default fit model, a set of pseudo-experiments are conducted using the default model in both the generation and fit. The systematic uncertainties are determined from the mean of the pull distributions of the pseudo-experiments scaled by the statistical uncertainty of that parameter in the fit to data. The observed deviations are included in the systematic uncertainties.

The systematic uncertainties are listed in Table 5. For each parameter, the total systematic uncertainty is obtained by adding all of the contributions in quadrature.

Table 5: Summary of systematic uncertainties assigned to the physical parameters of interest.

7 Results

The results and correlations of the physics parameters obtained from the fit are given in Tables 6 and 7. The estimate of the total number of B_s^0 meson candidates of $453\,570 \pm 740$ is given by multiplying the total number of events used in the fit by the extracted signal fraction and its statistical uncertainty. The fitted value of the B_s^0 mass is in a good agreement with world average value [26]. Fit projections, including the ratio plots, are shown in Figure 6 for the mass and proper decay time and in Figure 7 for the angles. The ratio plots show the difference between each data point and the total fit line divided by the statistical and systematic uncertainties summed in quadrature (σ) of that point. The deviations of ratio plots are within 2σ , which shows that the systematic uncertainties are properly evaluated and covering the model deviations.

8 Combination with 7 TeV and 8 TeV results

The measured values are consistent with those obtained in the previous analysis [10] using 19.2 fb⁻¹ of data collected at $\sqrt{s} = 7$ TeV and 8 TeV. A best linear unbiased estimator (BLUE) [41, 42] is used to combine the current measurements with those from the previous analysis. The measured values, uncertainties, and correlations are taken from the measurements performed at each centre-of-mass energy. The statistical correlation between these three measurements is zero as the events are different. The correlations of the systematic uncertainties between the three measurements are estimated and tested in several categories depending of whether the given systematic effect changed significantly between the measurements. The combined results for the fit parameters and their uncertainties are given in Table 8.

The two-dimensional likelihood contours in the ϕ_s - $\Delta\Gamma_s$ plane for the ATLAS result based on 7 TeV and 8 TeV data, the result from 13 TeV data, and the combined result are shown in Figure 8. The statistical and systematic uncertainties are combined in quadrature and correlations are taken into account in the construction of Gaussian contours. The correlation between the ϕ_s and $\Delta\Gamma_s$ values determined in combination is -0.04.

Two-dimensional likelihood contours in the ϕ_s - $\Delta\Gamma_s$ plane are shown in Figure 9 for this ATLAS result, the result from CMS [11] using the $B_s^0 \rightarrow J/\psi\phi$ decay, and the result from LHCb [12] using the

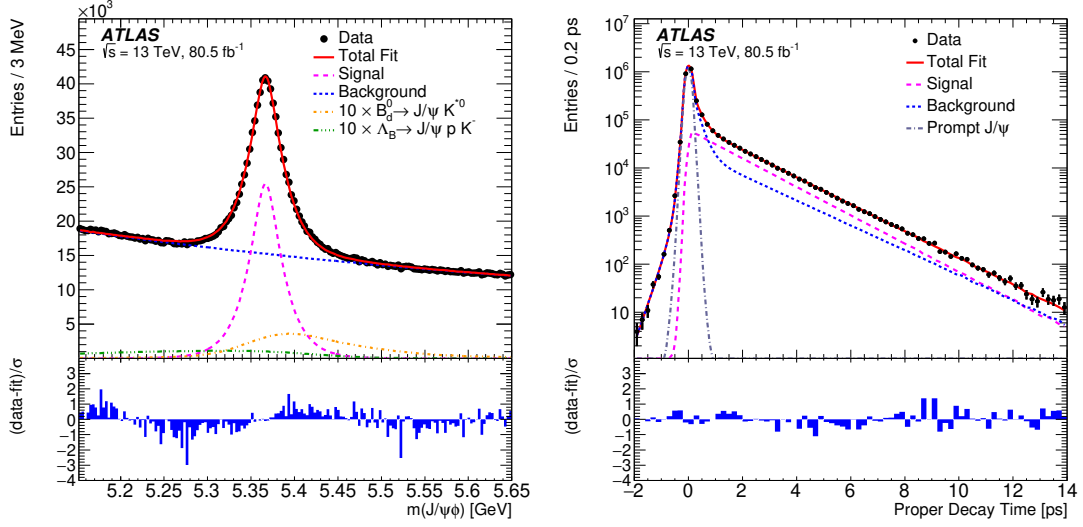

Figure 6: (Left) Mass fit projection for the $B_s^0 \rightarrow J/\psi \phi$ sample. The red line shows the total fit, the short-dashed magenta line shows the $B_s^0 \rightarrow J/\psi \phi$ signal component, the combinatorial background is shown as a blue dotted line, the orange dash-dotted line shows the $B_d^0 \rightarrow J/\psi K^{0*}$ component, and the green dash-dot-dot line shows the contribution from $\Lambda_b \rightarrow J/\psi p K^-$ events. (Right) Proper decay time fit projection for the $B_s^0 \rightarrow J/\psi \phi$ sample. The red line shows the total fit while the short-dashed magenta line shows the total signal. The total background is shown as a blue dotted line, and a long-dashed grey line shows the prompt J/ψ background component. Below each figure is a ratio plot that shows the difference between each data point and the total fit line divided by the statistical and systematic uncertainties summed in quadrature (σ) of that point.

Table 8: Values of the physical parameters extracted in the combination of 13 TeV results with those obtained from 7 TeV and 8 TeV data.

Parameter	Value	Statistical uncertainty	Systematic uncertainty
ϕ_s [rad]	-0.087	0.037	0.019
$\Delta\Gamma_s$ [ps^{-1}]	0.0640	0.0042	0.0024

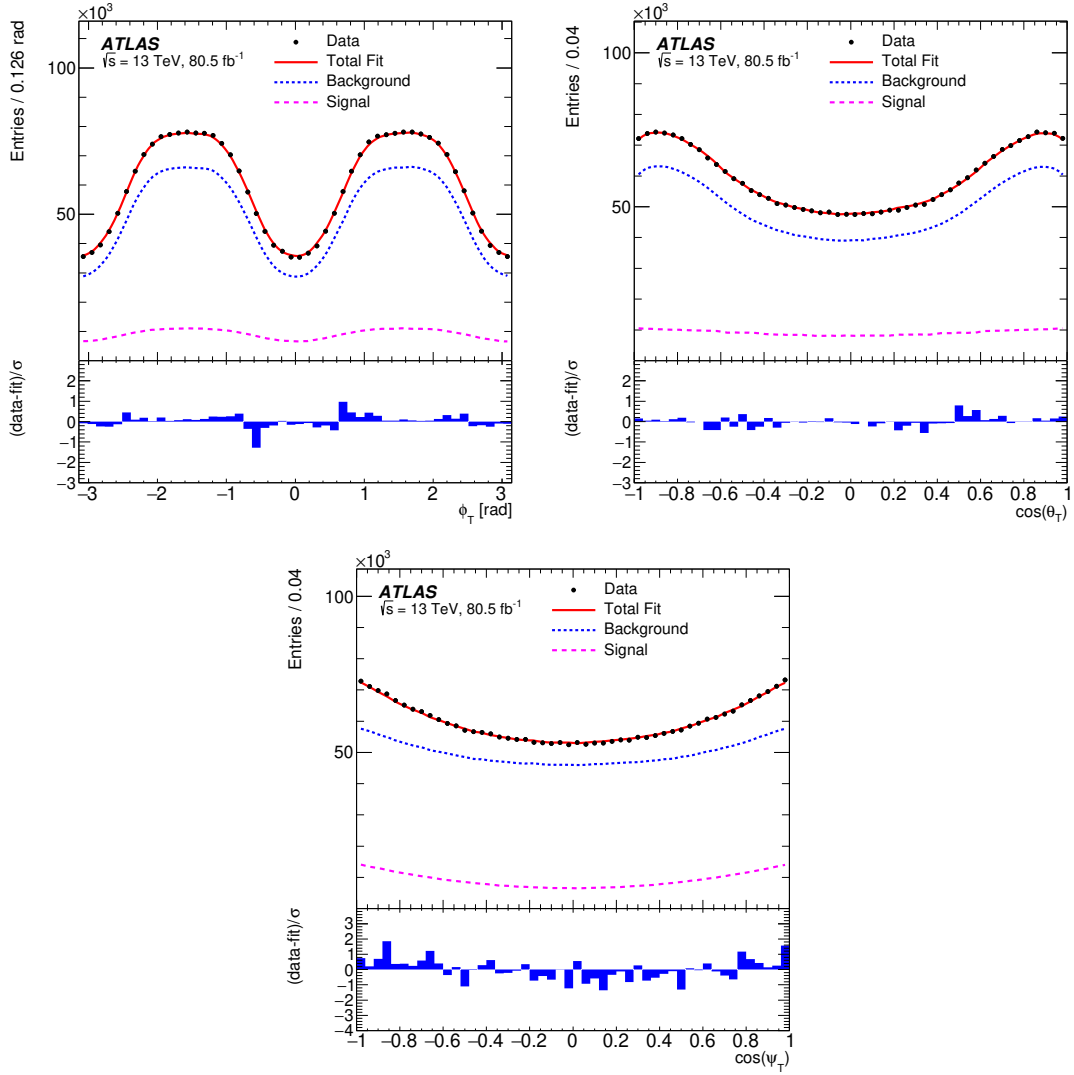

Figure 7: Fit projections for the transversity angles ϕ_T (top left), $\cos(\theta_T)$ (top right), and $\cos(\psi_T)$ (bottom). In all three plots the red solid line shows the total fit, the $B_s^0 \rightarrow J/\psi\phi$ signal component is shown by the magenta dashed line and the blue dotted line shows the contribution of all background components. Below each figure is a ratio plot that shows the difference between each data point and the total fit line divided by the statistical and systematic uncertainties summed in quadrature (σ) of that point.

Figure 8: Contours of 68% confidence level in the ϕ_s - $\Delta\Gamma_s$ plane, showing ATLAS results for 7 TeV and 8 TeV data (blue dashed-dotted curve), for 13 TeV data (green dashed curve) and for 13 TeV data combined with 7 TeV and 8 TeV (red solid curve) data. The Standard Model prediction [2, 5] is shown as a very thin black rectangle. In all contours the statistical and systematic uncertainties are combined in quadrature and correlations are taken into account.

$B_s^0 \rightarrow J/\psi K^+ K^-$ decay. The contours are obtained by interpreting each result as a two-dimensional Gaussian probability distribution in the ϕ_s - $\Delta\Gamma_s$ plane. All results are consistent with each other and with the SM [2, 5].

Figure 9: Contours of 68% confidence level in the ϕ_s - $\Delta\Gamma_s$ plane, including results from CMS (red) and LHCb (green) using the $B_s^0 \rightarrow J/\psi K^+ K^-$ decay only. The blue contour shows the ATLAS result for 13 TeV combined with 7 TeV and 8 TeV. The Standard Model prediction [2, 5] is shown as a very thin black rectangle. In all contours the statistical and systematic uncertainties are combined in quadrature.

9 Summary

This paper presents a measurement of the time-dependent CP asymmetry parameters in $B_s^0 \rightarrow J/\psi\phi$ decays from an 80.5 fb^{-1} data sample of pp collisions collected with the ATLAS detector during the 13 TeV LHC run. The values from the 13 TeV analysis are consistent with those obtained in the previous ATLAS analysis using 7 TeV and 8 TeV data. The two measurements are statistically combined, leading to the following results:

$$\begin{aligned}
\phi_s &= -0.087 \pm 0.037 \text{ (stat.)} \pm 0.019 \text{ (syst.) rad} \\
\Delta\Gamma_s &= 0.0640 \pm 0.0042 \text{ (stat.)} \pm 0.0024 \text{ (syst.) ps}^{-1} \\
\Gamma_s &= 0.6698 \pm 0.0014 \text{ (stat.)} \pm 0.0015 \text{ (syst.) ps}^{-1} \\
|A_{\parallel}(0)|^2 &= 0.2221 \pm 0.0018 \text{ (stat.)} \pm 0.0022 \text{ (syst.)} \\
|A_0(0)|^2 &= 0.5149 \pm 0.0012 \text{ (stat.)} \pm 0.0031 \text{ (syst.)} \\
|A_S(0)|^2 &= 0.0343 \pm 0.0032 \text{ (stat.)} \pm 0.0044 \text{ (syst.)} \\
\delta_{\perp} &= 3.21 \pm 0.10 \text{ (stat.)} \pm 0.05 \text{ (syst.) rad} \\
\delta_{\parallel} &= 3.36 \pm 0.05 \text{ (stat.)} \pm 0.08 \text{ (syst.) rad} \\
\delta_{\perp} - \delta_S &= -0.24 \pm 0.05 \text{ (stat.)} \pm 0.02 \text{ (syst.) rad}
\end{aligned}$$

The measurement of the CP -violating phase ϕ_s is consistent with the Standard Model prediction, and improves on the precision of previous ATLAS measurements.

Acknowledgements

We thank CERN for the very successful operation of the LHC, as well as the support staff from our institutions without whom ATLAS could not be operated efficiently.

We acknowledge the support of ANPCyT, Argentina; YerPhI, Armenia; ARC, Australia; BMWFW and FWF, Austria; ANAS, Azerbaijan; SSTC, Belarus; CNPq and FAPESP, Brazil; NSERC, NRC and CFI, Canada; CERN; CONICYT, Chile; CAS, MOST and NSFC, China; COLCIENCIAS, Colombia; MSMT CR, MPO CR and VSC CR, Czech Republic; DNRF and DNSRC, Denmark; IN2P3-CNRS and CEA-DRF/IRFU, France; SRNSFG, Georgia; BMBF, HGF and MPG, Germany; GSRT, Greece; RGC and Hong Kong SAR, China; ISF and Benozio Center, Israel; INFN, Italy; MEXT and JSPS, Japan; CNRST, Morocco; NWO, Netherlands; RCN, Norway; MNiSW and NCN, Poland; FCT, Portugal; MNE/IFA, Romania; MES of Russia and NRC KI, Russia Federation; JINR; MESTD, Serbia; MSSR, Slovakia; ARRS and MIZŠ, Slovenia; DST/NRF, South Africa; MINECO, Spain; SRC and Wallenberg Foundation, Sweden; SERI, SNSF and Cantons of Bern and Geneva, Switzerland; MOST, Taiwan; TAEK, Turkey; STFC, United Kingdom; DOE and NSF, United States of America. In addition, individual groups and members have received support from BCKDF, CANARIE, Compute Canada and CRC, Canada; ERC, ERDF, Horizon 2020, Marie Skłodowska-Curie Actions and COST, European Union; Investissements d’Avenir Labex, Investissements d’Avenir Idex and ANR, France; DFG and AvH Foundation, Germany; Herakleitos, Thales and Aristeia programmes co-financed by EU-ESF and the Greek NSRF, Greece; BSF-NSF and GIF, Israel; CERCA Programme Generalitat de Catalunya and PROMETEO Programme Generalitat Valenciana, Spain; The Royal Society and Leverhulme Trust, United Kingdom.

The crucial computing support from all WLCG partners is acknowledged gratefully, in particular from CERN, the ATLAS Tier-1 facilities at TRIUMF (Canada), NDGF (Denmark, Norway, Sweden), CC-IN2P3 (France), KIT/GridKA (Germany), INFN-CNAF (Italy), NL-T1 (Netherlands), PIC (Spain), ASGC (Taiwan), RAL (UK) and BNL (USA), the Tier-2 facilities worldwide and large non-WLCG resource providers. Major contributors of computing resources are listed in Ref. [43].

¹⁶⁸^(a)TRIUMF, Vancouver BC;^(b)Department of Physics and Astronomy, York University, Toronto ON; Canada.

¹⁶⁹Division of Physics and Tomonaga Center for the History of the Universe, Faculty of Pure and Applied Sciences, University of Tsukuba, Tsukuba; Japan.

¹⁷⁰Department of Physics and Astronomy, Tufts University, Medford MA; United States of America.

¹⁷¹Department of Physics and Astronomy, University of California Irvine, Irvine CA; United States of America.

¹⁷²Department of Physics and Astronomy, University of Uppsala, Uppsala; Sweden.

¹⁷³Department of Physics, University of Illinois, Urbana IL; United States of America.

- ¹⁷⁴Instituto de Física Corpuscular (IFIC), Centro Mixto Universidad de Valencia - CSIC, Valencia; Spain.
- ¹⁷⁵Department of Physics, University of British Columbia, Vancouver BC; Canada.
- ¹⁷⁶Department of Physics and Astronomy, University of Victoria, Victoria BC; Canada.
- ¹⁷⁷Fakultät für Physik und Astronomie, Julius-Maximilians-Universität Würzburg, Würzburg; Germany.
- ¹⁷⁸Department of Physics, University of Warwick, Coventry; United Kingdom.
- ¹⁷⁹Waseda University, Tokyo; Japan.
- ¹⁸⁰Department of Particle Physics, Weizmann Institute of Science, Rehovot; Israel.
- ¹⁸¹Department of Physics, University of Wisconsin, Madison WI; United States of America.
- ¹⁸²Fakultät für Mathematik und Naturwissenschaften, Fachgruppe Physik, Bergische Universität Wuppertal, Wuppertal; Germany.
- ¹⁸³Department of Physics, Yale University, New Haven CT; United States of America.
- ¹⁸⁴Yerevan Physics Institute, Yerevan; Armenia.
- ^a Also at Borough of Manhattan Community College, City University of New York, New York NY; United States of America.
- ^b Also at Centre for High Performance Computing, CSIR Campus, Rosebank, Cape Town; South Africa.
- ^c Also at CERN, Geneva; Switzerland.
- ^d Also at CPPM, Aix-Marseille Université, CNRS/IN2P3, Marseille; France.
- ^e Also at Département de Physique Nucléaire et Corpusculaire, Université de Genève, Genève; Switzerland.
- ^f Also at Departament de Física de la Universitat Autònoma de Barcelona, Barcelona; Spain.
- ^g Also at Departamento de Física, Instituto Superior Técnico, Universidade de Lisboa, Lisboa; Portugal.
- ^h Also at Department of Applied Physics and Astronomy, University of Sharjah, Sharjah; United Arab Emirates.
- ⁱ Also at Department of Financial and Management Engineering, University of the Aegean, Chios; Greece.
- ^j Also at Department of Physics and Astronomy, Michigan State University, East Lansing MI; United States of America.
- ^k Also at Department of Physics and Astronomy, University of Louisville, Louisville, KY; United States of America.
- ^l Also at Department of Physics and Astronomy, University of Sheffield, Sheffield; United Kingdom.
- ^m Also at Department of Physics, Ben Gurion University of the Negev, Beer Sheva; Israel.
- ⁿ Also at Department of Physics, California State University, East Bay; United States of America.
- ^o Also at Department of Physics, California State University, Fresno; United States of America.
- ^p Also at Department of Physics, California State University, Sacramento; United States of America.
- ^q Also at Department of Physics, King's College London, London; United Kingdom.
- ^r Also at Department of Physics, St. Petersburg State Polytechnical University, St. Petersburg; Russia.
- ^s Also at Department of Physics, Stanford University, Stanford CA; United States of America.
- ^t Also at Department of Physics, University of Adelaide, Adelaide; Australia.
- ^u Also at Department of Physics, University of Fribourg, Fribourg; Switzerland.
- ^v Also at Department of Physics, University of Michigan, Ann Arbor MI; United States of America.
- ^w Also at Dipartimento di Matematica, Informatica e Fisica, Università di Udine, Udine; Italy.
- ^x Also at Faculty of Physics, M.V. Lomonosov Moscow State University, Moscow; Russia.
- ^y Also at Giresun University, Faculty of Engineering, Giresun; Turkey.
- ^z Also at Graduate School of Science, Osaka University, Osaka; Japan.
- ^{aa} Also at Hellenic Open University, Patras; Greece.
- ^{ab} Also at Institutio Catalana de Recerca i Estudis Avancats, ICREA, Barcelona; Spain.
- ^{ac} Also at Institut für Experimentalphysik, Universität Hamburg, Hamburg; Germany.
- ^{ad} Also at Institute for Mathematics, Astrophysics and Particle Physics, Radboud University

Nijmegen/Nikhef, Nijmegen; Netherlands.

ae Also at Institute for Nuclear Research and Nuclear Energy (INRNE) of the Bulgarian Academy of Sciences, Sofia; Bulgaria.

af Also at Institute for Particle and Nuclear Physics, Wigner Research Centre for Physics, Budapest; Hungary.

ag Also at Institute of High Energy Physics, Chinese Academy of Sciences, Beijing; China.

ah Also at Institute of Particle Physics (IPP), Vancouver; Canada.

ai Also at Institute of Physics, Academia Sinica, Taipei; Taiwan.

aj Also at Institute of Physics, Azerbaijan Academy of Sciences, Baku; Azerbaijan.

ak Also at Institute of Theoretical Physics, Iliia State University, Tbilisi; Georgia.

al Also at Instituto de Fisica Teorica, IFT-UAM/CSIC, Madrid; Spain.

am Also at Istanbul University, Dept. of Physics, Istanbul; Turkey.

an Also at Joint Institute for Nuclear Research, Dubna; Russia.

ao Also at LAL, Université Paris-Sud, CNRS/IN2P3, Université Paris-Saclay, Orsay; France.

ap Also at Louisiana Tech University, Ruston LA; United States of America.

aq Also at LPNHE, Sorbonne Université, Université de Paris, CNRS/IN2P3, Paris; France.

ar Also at Manhattan College, New York NY; United States of America.

as Also at Moscow Institute of Physics and Technology State University, Dolgoprudny; Russia.

at Also at National Research Nuclear University MEPhI, Moscow; Russia.

au Also at Physics Department, An-Najah National University, Nablus; Palestine.

av Also at Physics Dept, University of South Africa, Pretoria; South Africa.

aw Also at Physikalisches Institut, Albert-Ludwigs-Universität Freiburg, Freiburg; Germany.

ax Also at School of Physics, Sun Yat-sen University, Guangzhou; China.

ay Also at The City College of New York, New York NY; United States of America.

az Also at The Collaborative Innovation Center of Quantum Matter (CICQM), Beijing; China.

ba Also at Tomsk State University, Tomsk, and Moscow Institute of Physics and Technology State University, Dolgoprudny; Russia.

bb Also at TRIUMF, Vancouver BC; Canada.

bc Also at Università di Napoli Parthenope, Napoli; Italy.
