Introduction

C1 esterase inhibitor deficiency (C1 inhibitor deficiency) is a rare disorder that may be genetic (hereditary angioedema, HAE) [1] or less commonly acquired (acquired angioedema, AAE) [2]. The disease has an estimated prevalence of 1 : 50 000; any ethnic group may be affected, and many cases are undiagnosed [3–5]. C1 inhibitor deficiency manifests with episodic attacks of bradykinin-mediated localized subcutaneous and/or submucosal swellings, with a predilection for the face, extremities, gut, genitals, oropharynx and upper respiratory tract [6]. Abdominal attacks are extremely painful and disruptive, while laryngeal swelling is life-threatening and accounts for the very significant lifetime mortality reported from historical data [6–8].

The evidence base for disease management has expanded significantly since the first UK consensus document was published in 2005 [9]. For acute therapy, extensive data are now available for two new drugs that target the bradykinin pathway [10–17], for two established plasma-derived C1 inhibitor replacement products [18–20] and for a novel recombinant C1 inhibitor concentrate product [21–23]. Further evidence supports the use of home therapy for acute attacks, an approach with clear benefits for patients and the wider health economy [24–28]. The effectiveness of regular C1 inhibitor concentrate injections for long-term
prophylaxis is now established more firmly, presenting an alternative to attenuated androgens for selected patients [19,29]. In parallel with these advances in medical management, focused research efforts have revolutionized our understanding of the impact of C1 inhibitor deficiency on the physical, emotional and economic health of patients and their families [5,30–34], thus informing the application of this improved evidence base.

A number of documents have translated these data into evidence-based guidelines [24,35–41], but none fully reflect the priorities and organization of services for C1 inhibitor-deficient patients in the United Kingdom. With these considerations in mind, the United Kingdom Primary Immunodeficiency Network (UK PIN – a cross-disciplinary professional association) and the patient group Hereditary Angioedema UK (HAE UK) jointly commissioned this project to update the 2005 UK consensus document.

Several considerations are particularly pertinent to the context of this document. The UK National Health Service (NHS) is dealing with unprecedented financial pressure, and while successive governments have continued to pledge commitment to a health-care system that is free at the point of demand, traditional hospital-based models of health care are unlikely to be affordable for the United Kingdom in the long term. Recent government initiatives have focused on community and patient-centred ‘integrated’ care, both as a means to ensure long-term affordability and to improve social and medical outcomes [42]. There has also been increased awareness of more rare diseases, with the needs of affected patients recognized in UK initiatives [43]. Finally, there is a perception that the provision of specialist services for C1 inhibitor-deficient patients varies geographically [44], with possible underlying factors including the availability of funding for high-cost drugs and the location of major centres of expertise.

In England, these considerations have contributed to radical reform of specialist services for patients with C1 inhibitor deficiency and other rare diseases: centralized funding has been devolved to NHS England, with the commissioning specification encouraging expert patient-centred care, coordinated by specialist centres that fulfil predefined standards [45]. The organization of services in other UK nations differs: in Wales, all patients access services at the Immunodeficiency Centre in Cardiff, with centrally commissioned resources transferred from Health Boards; in Scotland, patients access local services or travel across Unitary Health Board areas where this is not possible, with high-cost medicines accessed through a Pharmacy Board structure overseen by the Scottish Medicines Committee; in Northern Ireland, services are centralized to the Regional Immunology Service in Belfast, with a local process for the approval of high-cost drugs.

It was not felt appropriate to replicate the excellent work that has produced a plethora of recent evidence-based guidelines in the field of C1 inhibitor deficiency [24,35–41]. Instead, we sought to produce a UK-specific document that is complementary to existing guidelines. To achieve this aim, the guidelines have been produced using the Delphi method, a structured process that aims to produce consensus among a group of experts. We report here the consensus process and statements that were ultimately approved. This document, together with standards for specialist services issued by UK PIN [46], provides a framework for the management of C1 inhibitor-deficient patients in the United Kingdom.

**Methods**

The research design for the consensus was based on the Delphi method: respondents are presented with a series of statements, each of which is scored for agreement using a four-point Likert scale, as follows: strongly agree, tend to agree, tend to disagree, strongly disagree. Following the first round of responses, any statements considered contentious (typically less than 66% of respondents agree) may be reviewed, with the final list of statements representing the consensus.

The questionnaire was developed by the HAE Consensus Steering Group, which included a patient representative, eight physicians with a specialist interest in the disease and three specialist nurses. Throughout a day of discussion on 26 September 2012, the Steering Group agreed a total of 48 consensus statements across 11 themes. When developing these statements, the Steering Group considered developments in the evidence base, published guidelines for specialist services [45,46] and personal experiences. The statements were incorporated into a consensus questionnaire, with a slightly modified plain-language version generated for patient use. Questionnaires were sent to all UK-based physicians and specialist nurses known to be involved in the management of C1 inhibitor-deficient patients, and additionally to the membership of key professional organizations (Table 1). Patients were invited to express their opinion by HAE UK. Two subsequent opportunities to complete the questionnaire were provided by

Table 1. Professional societies invited to participate in the consensus process.
Results

Ninety-one health-care workers (51 consultant immunologists and/or allergists, 10 specialist registrars training in clinical immunology or allergy, 14 immunology specialist nurses, 16 other or unknown designations) responded, representing the majority of health-care professionals who care actively for this patient group. A total of 36 patients with C1 inhibitor deficiency responded. All four nations within the United Kingdom were represented among respondents.

The consensus statements are listed in Table 2. A high degree of consensus was obtained during the first round, with more than 90% of respondents indicating ‘strongly agree’ or ‘tend to agree’ to all the statements and few abstentions (Supporting information, Table S1). As all statements achieved consensus in excess of 90%, no iterative amendment was required. Consensus was highest among patient respondents, with more than 97% agreement to all statements. Among health-care workers, agreement of >90% was achieved in response to 47 of 48 questions; statement 20 – concerning use of anti-fibrinolytics in prophylaxis – achieved 88.8% agreement. In general, most statements elicited ‘strong agreement’, with ‘tend to disagree’ and ‘strongly disagree’ rarely observed. Consensus remained extremely high when analysed by occupation or speciality, although small numbers limit the interpretation of subgroup analysis.

Alignment of these statements to accreditation standards for specialist centres published by UK PIN is described in Supporting information, Table S2.

A facility for freetext comments was utilized by a minority of respondents to comment on the statements and study process: one respondent criticized the document for being too ‘centralist’ and another suggested that the definition of ‘specialist centre’ should be kept flexible enough to allow for different models of care. Some questions (for example, concerning children or new medications) were indicated as inappropriate for those without specific expertise. We note that some respondents did not comment on all statements, presumably denoting lack of expertise or opinion with regard to a particular statement (see Supporting information, Table S1).

Discussion

We present here an updated UK consensus for the management of patients with C1 inhibitor deficiency. The consensus was developed using the Delphi method, an established process for the collation of opinion from a group of experts. According to this process, respondents indicate agreement with statements in rounds; after each round, facilitators collate and anonymize the responses to guide amendment of the statements for future rounds. The process is completed when predefined levels of consensus are reached. This method was pursued in order to produce guidelines that are complementary to recent publications [24,35–41] and with an emphasis on UK services.

The consensus has evolved significantly since the previous 2005 UK document. A particularly important development is an improved evidence base to guide the management of acute attacks. The dosing of C1 inhibitor concentrate (statement 17) was particularly emphasized, given the availability of guidance from robust trial data [18–21]. However, clinical experience suggests that individualized dosing is appropriate, including higher doses where treatment is delayed and lower doses when treatment is immediately available (statement 18). In keeping with other recent guidelines [24,35–41], the document supports the wider use of acute treatment for disabling attacks (statement 3) rather than limiting treatment to severe episodes. Statement 2 (treatment of HAE should follow international guidance and standards, while considering the resources available in the United Kingdom) and statement 12 (patients should take medication according to clinical need rather than financial considerations) could perhaps be considered to conflict. We would emphasize, however, that as currently worded, the consensus for statements 2 and 3 does not mandate treatment for all attacks – rather, less serious attacks are considered to be potentially treatable.

Consideration of treatment costs will form part of the decision process when weighing up whether or not symptoms are sufficiently disabling to warrant therapy within the parameters of statement 12. Regarding long-term prophylaxis, the value of closely monitored androgens with appropriate monitoring is endorsed (statements 21–25). A greater emphasis is placed on long-term prophylaxis with C1 inhibitor concentrate (statement 27), reflecting an improved evidence base [19,29] and increased experience among clinicians and patients. Long-term prophylaxis with tranexamic acid continues to be supported in the paediatric setting where options are limited (statement 46). A more guarded statement was supported (with 88.9% consensus among health-care workers) for the general use of this agent for long-term prophylaxis (statement 20); this was the only statement to achieve consensus below 90%, reflecting a weak evidence base and mixed practice.

Saule and colleagues published an observational series including 16 women with hereditary angioedema, describing modest benefit from progestagens in long-term prophylaxis [47]. The authors recommended either desogestrel 75 mg daily (Cerazette), medroxyprogesterone acetate (Depo-Provera) or norethisterone 10 mg daily. The latter two options provide a higher dose and possibly a higher
Table 2. 2014 C1 inhibitor deficiency consensus statements.

A: Treatment objectives
1. Each C1 inhibitor-deficient patient should be able to manage his or her symptoms proactively in such a way that they maintain personal safety and minimal disruption in living a healthy and productive life.
2. Treatment of HAE should follow international guidance and standards, whilst considering the resources available in the UK.
3. All disabling attacks irrespective of location are eligible for treatment as soon as they are clearly recognized.
4. Patient self-treatment is the ideal service model in line with government policy.

B: Access to expertise
5. Every patient should be under the supervision of a specialist hub centre for HAE, either directly or via a spoke centre.
6. A specialist centre has appropriate resources and a sufficient cohort of patients to maintain appropriate expertise in the treatment of HAE.
7. Informative educational literature and support should be made available to every HAE patient.
8. People with suspected HAE need to have access to a specialist centre expert.
9. Every patient (including children) should be offered the option of home administration with appropriate monitoring, training and governance.

C: Access to medication
10. Every patient should hold a safe quantity (minimum of one) of acute treatment doses at home dependent on individual needs.
11. It is important that arrangements are in place to facilitate speedy replacement of acute attack medication after use so that the patient may proactively manage their symptoms safely with minimum disruption to living a healthy and productive life.
12. Patient should take their medication according to clinical need rather than financial considerations.

D: Acute treatment
13. Plasma-derived C1 inhibitors (Berinert, Cinryze), recombinant C1 inhibitor (Ruconest) and Icatibant (Firazyr) are all acceptable options for acute treatment.
14. Icatibant may be particularly useful in enabling self-administration as intravenous access is not necessary.
15. Regular prophylactic treatment with C1 inhibitor may be appropriate for patients requiring treatment for two or more attacks per week.
16. Plasma-derived C1 inhibitor is the treatment of choice for acute attacks of HAE for children, pregnant and breast-feeding women, and those trying to conceive.

E: Dosing of C1 inhibitor
17. We recommend that patients use the licensed dose of C1 inhibitor. In certain circumstances, the dose may need adjustment according to clinical response.
18. A higher dose may be required if treatment is delayed. For early treatment via self administration, lower doses may be appropriate.
19. If a second dose is needed, then the full dose will be required. It may therefore be a false economy to dose inappropriately low in the first instance.

F: Long-term prophylaxis
20. Evidence for the efficacy of anti-fibrinolytics is poor; however, a minority of patients may find them helpful.
21. Attenuated androgens are effective in long-term prophylaxis for most people.
22. The lowest effective dose of attenuated androgen should be used to minimize side effects.
23. High doses of androgens may provoke severe side effects without added benefits.
24. Doses of danazol above 200 mg daily should be exceptional.
25. Doses of stanozolol above 4 mg daily should be exceptional.
26. Treatment registries should be completed to allow better understanding of new products.
27. Exceptionally, C1 inhibitor prophylaxis may be required when control of acute attacks is not possible by other means (including for children). This should be reviewed at regular intervals.

G: Treatment plans
28. All patients should have a treatment plan for acute and elective surgery, including dentistry.
29. All patients should have an additional treatment plan in place to ensure their safety when away from home or abroad.
30. Treatment plans should be developed according to individual need and updated regularly.

H: Role of the specialist nurse
31. The specialist immunology nurse is pivotal in patient care.
32. All patients should have timely access to a specialist immunology nurse.
33. The specialist immunology nurse has a key role in supporting the patient and their family in the practicalities of living with HAE to achieve the best quality of life.

I: Patient support
34. Because HAE is a rare condition, patient information should be comprehensive and consistent.
35. HAE patients benefit from direct contact with others with the same condition.
36. Advocacy is important in ensuring equality of access and benefit.
37. Patients may have inappropriately low expectations of QoL with HAE, which may limit their life options. This should be addressed.
38. Patient information should be provided in an easily accessible and up-to-date format including electronic media.
39. Specialist HAE patient support groups such as HAE UK have an important role in disseminating best practice in partnership with health care professionals.
response rate. A statement about the role of progestagens as long-term prophylaxis was not included in this document because the relevant paper was not published at the time of the steering group meeting.

The results also indicate strong consensus on aspects of service organization and delivery, showing overwhelming support for specialist services (statements 5–9), and patient self-management and home therapy (statement 4). We welcome the principle of patient-centred, community-based care, supported by easily accessible specialist expertise and, where appropriate, local centres. The haemophilia model of self-administration of intravenous medications by patients and their families demonstrates that this model is feasible and cost-effective. The net financial effects of such an approach as applied to C1 inhibitor deficiency in the United Kingdom have not been defined, but data from Denmark demonstrate the benefits of the approach in reducing hospital attendance and the burden of disease [48]. The results of the consensus indicate clearly that both patients and health-care workers endorse this model for C1 inhibitor deficiency, in order to ensure that patients can achieve their full potential by early education and training in the prevention and management of acute attacks.

Some important performance characteristics of the Delphi method should be considered. The consensus involves scientific evidence, but does not involve rigorous review of scientific evidence in order to produce guidance. This has produced a document that is complementary to existing guidelines from other bodies. It does not seek to replicate or replace their work, but rather adds another form of expert opinion evidence to the literature. Compared to the generation of evidence-based guidelines by small panels of experts, the Delphi method is more inclusive and gathers opinion from a larger number of professionals. The anonymity of respondents may temper domination of the process by opinion leaders and encourages free expression. However, the issue is not completely resolved, as the question set is determined by a steering group.

Another key difficulty is selection of the panel members: a very inclusive process may produce an invalid consensus by including responses from respondents who lack expertise in the field, whereas an overly exclusive process may not reflect a true consensus. We attempted to engage with a wide variety of stakeholders outside the clinical immunology and allergy community by collaborating with relevant professional bodies, distributing paper copies at professional meetings and permitting peer-to-peer distribution of questionnaires. A significant number of responses was obtained from outside the immunology and allergy community which, in addition to 51 responses from clinical immunologists and/or allergists, is felt to capture the large majority of health-care workers involved directly in the management of this disease. As these respondents work independently in specialist centres throughout the United Kingdom, we can be confident that the remarkably high consensus does not reflect training or service led by small number of opinion leaders. However, it must be acknowledged that the UK allergy and immunology community constitutes a small group with a long-standing tradition of cooperation through organizations such as UK PIN. In addition, the methodology does not permit the calculation of a defined response rate. Compared to the health-care worker data set, results from patient respondents are less robust due to relatively small numbers (n = 36) and the risk of ascertainment bias.

The assumption that all participants are equal in terms of knowledge and experience represents another weakness of the methodology. This probably accounts for a relatively high number of abstentions among respondents for several more technical statements, notably 24, 25, 45 and 46. Finally, where successive rounds are utilized, the risk is that the process may mould, rather than simply collate, opinion; this was not a concern in this project, as consensus was reached within a single round. Despite the shortcomings, the very high level of consensus among healthcare workers and a small sample of patients indicate strong alignment of opinion.

This project has not addressed explicitly hereditary bradykinin-mediated angioedema that is not related to C1 inhibitor deficiency [49], but many of the statements would be applicable to this group, whose specific needs

are also addressed in a separate consensus document [50]. Although the document is UK-centric, the themes of quality improvement, patient-centred care and increasing health-care costs are a focus and challenge for most higher-income nations at the current time.

While responses are confidential and not individually available to the steering committee, those responding have been invited to support this paper publically. Sixty-four of 91 health-care professionals indicated their publicly declared support and are listed (Table 3) as the UK 2014 C1 Inhibitor Deficiency Consensus Group.

Acknowledgements

The authors, UK PIN and HAE UK extend sincere gratitude to the patients and colleagues who completed the consensus questionnaire. We are grateful to Dr Richard Herriot for valuable suggestions and to Tim Warren and Simon Gwynn of Triducive Ltd for facilitating the process. The project was supported by HAE UK.

Disclosures
