## Abstract

In this paper, we explore the concept of 'powerful knowledge' that from a Curriculum Studies perspective refers to the aspects of content knowledge towards which teaching should be oriented. We then consider how the concept of 'powerful knowledge' can be developed and operationalized as a research framework within studies in subject-specific didactics across the curriculum by relating it to the analytical concept of 'transformation'. Transformation is perceived in this case as an integrative process in which the content knowledge is transformed into knowledge that is taught and learned through various transformation processes outside and within the educational system. We argue that powerful knowledge cannot be identified based on the discipline alone, but needs to consider the transformation processes and be empirically explored. A variety of theories and frameworks developed within the European research tradition of didactics are described as ways to study transformation processes related to powerful knowledge at different institutional levels as well as between different subjects and disciplines. A comparative research framework related to subject specific education is proposed around three research questions.

**Keywords:** curriculum theory, powerful knowledge, school subjects, subject didactics, transformation

## Introduction

From the perspective of subject didactic research, which we also refer to as “research on subject specific education<sup>1</sup>” we outline an empirical research framework building on the concepts of powerful knowledge and transformation across school subjects. Powerful knowledge as an idea was coined by Michael Young (2009) to re-establish the importance of knowledge in teaching and curriculum development. Powerful knowledge is defined by Young as a subject specific coherent conceptual disciplinary knowledge that when learnt will

---

<sup>1</sup> The term *research on subject specific education* (ROSE) was selected to communicate and frame the interdisciplinary research area of subject didactics at Karlstad University, <https://www.kau.se/en/rose>

empower students to make decisions, and become action-competent in a way that influence their lives in a positive way.

In this article we develop the concept of powerful knowledge in two important ways. First, instead of only discussing powerful knowledge as an idea related to educational practices, we take a research position suggesting that powerful knowledge could be used as a framework in educational research related to subject specific education. In doing so we, in line with Deng (2015), propose to align the curricular concept of powerful knowledge to the European research tradition of didactics in general, and subject didactics in particular. Second, we develop the concept of powerful knowledge by refuting the dichotomization suggested by Young (2015b, p. 104) that curriculum ('what to teach') can be separated from pedagogy ('how to teach'). Instead we view these two questions as interrelated in didactical research.

We suggest an expansion of the concept of powerful knowledge by using the analytical concept of transformation as a key concept in describing powerful knowledge in different disciplines, institutions and school subjects. The reason for this is that the concept of transformation takes into consideration the didactization of the disciplinary knowledge, i.e. how it is transformed into something that is teachable and relevant for students. Thus, the criteria for selecting powerful knowledge to be adopted should reflect its relationship to the transformation process, e.g. what is possible for students to learn, what is relevant for students, what is part of the curriculum? Transformation is in this paper defined as an integrative process in which the content knowledge is transformed into knowledge that is taught and learned through various transformation processes outside and within the educational system in relation to individual, institutional and societal level. Here, we understand 'content knowledge' in a wider conceptual sense not only referring to factual knowledge. Such processes of transformation are apparent in concepts related to a number of different frameworks including: 'transposition' (Chevallard 1989; 2007), 'omstilling' (Ongstad 2006) and 'reconstruction' (Duit et al. 2012) and are also reflected in the work of Bernstein (1971) in relation to the concept of 're-contextualisation'. Our definition of transformation is purposely broad and inclusive in order to make it possible to relate to these various concepts representing different frameworks. In this paper there is no possibility to elaborate on how these frameworks relate to each other, but we will rather focus on the relationship between powerful knowledge and transformation. The school subject is never a simple reduction of the discipline. The content knowledge is always transformed to fit the educational purpose of teaching. Hence, to study the concept of powerful knowledge within school subjects we need to study its transformation processes, and address the *why* question ('why to teach') in addition to the *what* and *how* questions.

Moreover, the concept of powerful knowledge and the transformation processes the content of powerful knowledge undergo, must be placed in a wider context, where questions addressing societal challenges are raised. In a changing society the argument is being made that it is not obvious that powerful knowledge only stems from academic disciplines. For example, how does the emerging and rapidly changing media landscape affect frames for teaching and learning and how could powerful knowledge be understood in a connected classroom? How should interdisciplinary topics such as sustainability and migration be taught and organized in school? In a broad perspective, these questions can be described as powerful, while in the same time also being of multi- and cross-disciplinary nature and therefore needing to be approached in this way. What is powerful knowledge in such topics then emerges as a relevant question.

We will first outline the concept of powerful knowledge, thereafter we will elaborate on the different didactical theories and frameworks that address transformational processes in the educational system – from how knowledge is transformed from society, and between institutions into schools, and further how the knowledge is transformed within the schools and classrooms and how this influences the idea of powerful knowledge. We will relate the two key concepts to each other and then propose some important areas for empirical research as part of a research framework for future studies.

## **Powerful knowledge**

The notion of ‘powerful knowledge’ was coined by Young (2009) as a way to restore the importance of knowledge and teaching in curriculum development and research. The concept of powerful knowledge relates to aspects of conceptual knowledge that teaching should orient to. In discussing the question of what knowledge school students are entitled to have access to it is argued that ‘in all fields of enquiry, there is better knowledge, more reliable knowledge, knowledge nearer the truth about the world we live in and to what it is to be human’ (Young, 2013, p. 107). Furthermore, it is argued that this knowledge is always fallible and open to challenge and the difficulty of holding these two ideas together is highlighted. The concept of powerful knowledge is based on two key characteristics, which are both expressed in the form of boundaries. Firstly, this knowledge is specialized both in how it is produced and transmitted and this specialization is expressed in terms of the boundaries between disciplines and subjects which define their focus and objects of study. It is stressed that this is not general knowledge and that the boundaries are not fixed and unchangeable (Young 2013). It is also emphasized that cross-disciplinary research and learning depend on discipline-based knowledge. The second characteristic is that it is differentiated from the experiences that pupils bring to school or older learners bring to college or university. It is also stressed that this differentiation is expressed in the conceptual boundaries between school and everyday knowledge (Young 2013). We see this as one of the strengths of the concept of powerful knowledge; that it highlights the importance of the disciplinary knowledge in educational sciences in general and subject didactics in particular. Furthermore, this disciplinarily knowledge needs to be defined, problematized and structured before teaching. After defining how powerful knowledge is described in the work of Young, we will now elaborate on the motives behind its formulation.

### ***Powerful knowledge as the third way***

Young identifies two main traditions or approaches in recent debates about knowledge in educational sciences and philosophy. These traditions are extrapolated as trajectories into possible futures. In the first tradition, denoted Future 1, knowledge is, according to Young and Muller (2010), underpinned by an ‘under-socialized’ epistemology and defined as fixed sets of verifiable propositions or concepts that in teaching are evaluated through standardized testing. The second tradition, denoted Future 2, arose as a response to the first, and Young and Muller (2010) claim that the epistemology of knowledge is ‘over-socialized’ in that the character of knowledge is reduced to ‘who knows’ and the identification of knowers and their practices. Both these approaches can be viewed as deficient according to Young (2015a, b).

Future 1 has been shown to be unable to motivate and engage students with the body of knowledge to be learnt, and does not provide students with knowledge to tackle complex problems of society today (Young, 2015a, b). The alternative approach, Future 2, suggests integration of school subjects, promotion of generic skills and facilitative teaching that according to Young and Muller: “against their best intents, the main effects of Future 2-ists – those endorsing progressive pedagogy and its variants – are to render the contours of knowledge and learning invisible to the very learners that the pedagogy was designed to favour” (Young and Muller 2010, pp. 18-19). As a response to these deficient ways of organizing and investigating curriculum, Young and Muller suggest a social realist theory that: “sees knowledge as involving sets of systematically related concepts and methods for their empirical exploration and the increasingly specialized and historically located ‘communities of enquirers’” (Young & Muller, 2010, p. 14). Young denotes this alternative approach as a Future 3 solution. As a result, the most important part of such a curriculum making and thus educational research is to identify what constitutes ‘powerful knowledge’ in different school subjects.

In this paper we argue, in line with Young, that the return of knowledge in curriculum research is a step in the right direction. Since teaching is always ‘about something’, this ‘something’ is one of the most central issues of teaching, and powerful knowledge, we believe, is a useful analytical concept for determining this ‘something’. According to Young (2015a, p. 74) powerful knowledge can be referred to as: “features of the particular knowledge itself that is included in curriculum and what it can do for those who have access to it.” Further: “Knowledge is ‘powerful’ if it predicts, if it explains, if it enables you to envisage alternatives” (2015a, p. 74). To accomplish these goals Young characterizes powerful knowledge as distinct from common sense knowledge, proposing that it is systematic and its concepts are coherently related to each other, and finally it is specialized and related to specific disciplines. In doing so he draws on the ideas from Bernstein (1999) that disciplines have specific borders of concepts, contents and skills, and that it is within these borders that new scholarly knowledge is produced. Further, Young (2015a, b) claims that it is along these borders that knowledge becomes visible and meaningful to the learner and teaching in school and should therefore be organized in subjects closely related to the academic disciplines. Hence, powerful knowledge is clearly linked to the academic disciplines. On the other hand, as seen from the quotes above, powerful knowledge is also defined as ‘knowledge of the powerful’, i.e. its capacity to empower students. It is in the light of this latter perspective and slightly different way of describing the concept that we suggest in this article to develop the concept into a more flexible idea that can take different meanings in different contexts or situations, by relating powerful knowledge to the concept of transformation.

During recent years the idea of powerful knowledge has generated great interest among scholars (i.e. Deng, 2015; Nordgren, 2017) and has been suggested to be a powerful concept in the teaching of traditional subjects such as geography and history (Lambert, 2015; 2016; Counsell, 2011) as well as for coping with multidisciplinary topics such as interculturality (Nordgren, 2017). However as far as we can see there have been few empirical studies conducted in order to outline what powerful knowledge might be in different school subjects. Studies conducted to test whether powerful knowledge has the positive effects on students learning, as suggested by Young, have yet to be conducted. Accordingly, in this paper we outline a research framework that focuses on how powerful knowledge is manifested at different levels of the educational system by relating powerful knowledge to the concept of didactic transformation. We argue that any successful theory that suggests changes in the

educational system needs to be based on empirically based conclusions rather than only on theoretical underpinnings.

### ***The need for a holistic perspective***

As previously noted Young (2015b, p. 97) makes a very clear distinction between curriculum and pedagogy, and argues that they should be regarded as separate:

it is teachers in their pedagogy, not curriculum designers, who draw on their everyday knowledge in helping them to engage with the concepts stipulated by the curriculum and to see their relevance.... the knowledge stipulated by the curriculum must be based on specialized knowledge developed by communities of researchers. This process can be described as curriculum recontextualization”.

From our perspective, this dichotomization between curriculum and pedagogy as well as teaching and learning is not fruitful since most of the outcomes of teaching, i.e. the powerful knowledge that students acquire through their teaching, depends not only on the knowledge and the teacher, but also on the learner and the milieu (Brousseau, 1997). Deng criticizes this aspect in Young’s writing, arguing that: “they fail to explain how powerful knowledge has to be unlocked and transformed to bring about the cultivation of such capacities” (Deng 2015, p. 775). It is argued further that “it needs a theory of content that concerns how knowledge is selected and transformed into curriculum content, what educational potential content has, and how such potential can be disclosed or unlocked for the development [of students intellectual and moral powers or capacities]” (Deng 2015, p. 775). Hence, Deng argues for an extension of the social realist theory of powerful knowledge to better account for 1) the process of recontextualisation of the body of knowledge put to use in education, and 2) the process of teaching and learning in the classroom. Young’s answer to the first quest is more of obliviousness, or as Nordgren (2017, p. 4) concludes: “Young...becomes vague when shifting to areas where the transformation to education takes place”. For Deng’s second quest Young’s response is the dichotomization between curriculum and pedagogy, leaving pedagogy, or the *How* question, out of the picture. We adhere to the propositions of Deng that the theory of powerful knowledge should be developed and in this article propose a suggestion that addresses Deng’s two quests by relating powerful knowledge to the extensive European research tradition of didactics. In such a tradition the process of transformation of content knowledge, come into focus.

## **Transformation**

Powerful knowledge has mostly been described as a curriculum principle (e.g. Young 2015a). We think the principles behind powerful knowledge are well argued for as discussed above. However, we suggest that these principles need to be evaluated through educational research, and expanded into a teaching and learning practice because the school subjects are not mere reductions of the academic disciplines (Sjøberg 1998). In this part of the paper we will explicitly address that challenge, by considering powerful knowledge in relation to the concept of transformation.

Firstly we need to make clear that we do not use the concept of transformation as outlined by Mezirow (1991) in his ‘transformative learning theory’. Transformative learning theory is a

psychological theory about how individuals learn by changing their frames of reference by critically reflecting on their assumptions and beliefs and consciously making new ways of defining their worlds (Mezirow 2000), which is more in line with a future 2 perspective. Transformative learning has most often been used in an activist perspective in which education is seen as a mean to change or transform the society or the world (e.g. Mayo 1997). Instead, we are viewing transformation as a process of knowledge rather than the transformation of the individual or society. However, in order to understand and explain this transformation we recognize the need to consider also the complex relations with the learner as well as the educator as highlighted in didactical research, so there are overlaps with transformative learning theory.

Transformation is in this paper defined as an integrative process in which the content knowledge is transformed into knowledge that is taught and learned through various transformation processes outside and within the educational system in relation to individual, institutional and societal level. Hence, the concept transformation is in this paper understood in somewhat broader terms than it is framed in the framework of ‘pedagogical content knowledge’ (PCK) by Shulman (1986). Instead of simply considering transformation as something that is all about “how” a certain teaching content is to be represented in the classroom as in PCK, we also link ‘transformation’ to the other didactical questions: why? what? for who? and when? In our view transformation involves dimensions of significance, in relation to what content in the curriculum is important and what content ought to be taught. To be able to make those choices, decisions have to be made on why. In other words, what is the overarching purpose of schooling and of the subject or topic taught?

Rarely is the answer to that question found within a societal context, or in the academy. Further, questions of what and why have to be connected to the aspects of teaching traditions and methods (how?), the background of students (who?) and the concrete teaching situation (when?). From a didactical viewpoint, which is the position taken here, transformation is perceived as part of an integrative didactical process (Hudson, 2002, 2016). Hence, we argue that the curriculum principle of powerful knowledge is not evident by just looking at the academic discipline. Instead, we argue that the question of what constitutes powerful knowledge is an empirical question that can be answered fully only by addressing the transformation process and these four central didactical questions.

Additionally, it is of importance to recognize the fact that transformation takes place at different interrelated levels inside and outside of the educational system, as outlined in the Anthropological Theory of Didactics (ATD) (Chevallard, 2002). In ATD the concept of co-determination is used to analyse how knowledge is transposed within and outside the educational system at multiple levels (Artigue & Winsløw, 2010). From an analytical perspective, it is difficult to analyse at all those levels simultaneously. Instead, we would claim that three main levels can be discerned: *the societal, the institutional and the classroom level*. From a theoretical standpoint, the levels are of equal importance for learning outcomes (Bosch & Gascón, 2014), though emphasis in this paper will be placed on the classroom level, which is the focus of educational research. We will discuss educational transformation processes in relation to different perspectives, mostly rooted in the German/Nordic ‘didaktik tradition’ and French tradition of ‘didactiques des disciplines’.

### ***Transformation on a societal level***

The contribution of ATD in didactical research is that it points out the possibility that it is factors outside the classroom or even school that influence the way powerful knowledge

might be taught or understood. Hence, in our ambition to outline the transformation of powerful knowledge, ATD provides a framework to consider the societal perspective which we argue has been neglected in relation to the concept of powerful knowledge so far.

Education and educational research face a number of challenges due to the globalisation of the society. This has led education in a direction towards a future 2 trajectory (as discussed previously) that focuses on generic skills as a way to cope with an unpredictable future and rapid changes of societies. As Selander wrote: “It seems obvious that our current society is in a stage of change that requires new understandings of knowledge, learning and identity formation” (2008, p. 267). The underlying idea of this trajectory is that focus is turned away from knowledge to the individual learners’ needs and skills. As Kress (2008, p. 256) points out: “The emblematic sign of that change is the shift of emphasis in educational rhetoric from teaching to learning.” In addition the argument is being made that the globalization process leads to transfer of people, ideas and artefacts across all kinds of borders eroding the boundaries between subject disciplines. In response teaching and curriculum need to address contemporary multidisciplinary topics such as migration, interculturality, sustainability etc. Answers to these contemporary problems are found in many subjects, not only one. Moreover technological changes in society, such as digitalization have changed communication patterns, increased accessibility, knowledge and information flow within classrooms (Olin-Scheller, Sahlström & Tanner, forthcoming). The content knowledge regarded as powerful might be different in a digitalized classroom compared to a non-digitalized classroom. While the world is a complex and an interconnected system, research, academic disciplines and education focus on individual subjects, rather than cross-disciplinary themes. These societal demands on the adaptation of education to a changing world have led to the development of curriculum focusing on the development of generic competences and skills (Hargreaves, 2003).

Young criticizes this development: “such curricula, which quite explicitly blur the curriculum/pedagogy distinction, will inevitably lack coherence and be limited as a basis for pupils to progress. The basis for choosing topics or themes would be largely arbitrary” (Young 2015b, p. 103). However, Young himself recognizes that his idea of powerful knowledge and re-conceptualizing of a subject-based curriculum does not address the global transformations of society and how different subjects should relate to overlapping thematic issues (see Young 2015b, pp. 103-109), and he concludes: “The ‘connection’ problem has no easy solution, and there is no evidence that intellectual specialization is likely to go in reverse. For schools, I suggest, it is a pedagogic not a curriculum problem” (Young, 2015b, p.104). Here we disagree with Young and suggest that by including the idea of didactical transformation, powerful knowledge can be developed as an analytical concept to underpin empirical investigations. We suggest that these multidisciplinary issues are of great societal importance, and this is exactly where empirical research should start to explore the concept of powerful knowledge. An important question to address is whether knowledge linking to different school subjects relating to the same cross curricula topic (e.g. sustainability, migration) is powerful or not? The answer to that question would give significant insight to the possible prolificacy of the theory of powerful knowledge. If powerful knowledge relating to a theme differs to great extent between different school subjects, it would provide strong support for implementing a Future 3 based curriculum. Therefore, we claim that a comparative perspective is important when researching powerful knowledge. It is important to investigate relationships between content-specific and generic features of teaching, as well as how it occurs in different subjects.

Thus, for a relevant research framework we conclude that both a subject-specific and a cross-disciplinary perspective in relation to these societal challenges of how powerful knowledge is manifested in teaching and perceived by students and teachers is of importance to explore.

### *Transformation on an institutional level*

Transformation can also be understood as a process connected to the level of institutions. An institution can for example be a school, a ministry, the research community, a college etc. Hence, we here use a definition including both informal and formal institutions that promote mechanisms of social order and behaviour (North, 1990). The interplay between different settings or levels and how the knowledge is transformed between them is an important perspective in French tradition of didactiques des disciplines. The concept of 'didactic transposition' was introduced by Chevallard (1991; 2007) to capture the notion that an object of learning, a certain packet of knowledge that tends to be transformed depending on the institutional setting. The theory of didactic transposition was a precursor of ATD theory (as previously discussed) and both points out the importance of investigating institutions above the classroom in didactical research. Therefore, to be able to understand the process of transformation and its outcomes it is necessary to undertake an analysis in relation to the relevant institutional context. The process of transformation is in that sense embedded and mutually dependent on the institution in which it is reproduced.

Transposition is seen as a key concept in the French tradition of didactiques des disciplines (Hudson, 2016, p 115). In the school context, this knowledge is not knowledge for acting and solving problems in the social contexts in which it was created and where it is used, but it is transposed into knowledge to be taught and to be learned in the school institution. The concept of didactic transposition is based on the recognition that this 'rupture' between daily life and school changes the knowledge profoundly. This we would argue is central to the concept of powerful knowledge. In curriculum theory in general, and powerful knowledge as a curriculum principle in particular, the content knowledge of the discipline is not distinctively separated from the school subject content (i.e. Young 2015a,b). Instead it is often treated as the same. In our proposed research framework we see this elaboration of powerful knowledge as a central starting point for research, i.e. that what is regarded as powerful knowledge might be regarded differently by actors in different institutions. For example, Gericke (2009) showed in a study of biology education that the framework of Mendelian genetics is mostly presented in school textbooks, though this framework only has limited validity within most biological disciplines at the university level where Molecular genetics is most often used. The reason for this is to be found in the didactical transposition of knowledge between institutions.

The institutional level is important since it might constrain or prompt the kind of knowledge that is possible to teach in the classroom. In a study conducted by Achiam et al. (2016) they showed how objects in science teaching consisting of palaeontological specimens of *Archaeopteryx* fossils prompted scientific activities or trajectories in students learning. Hence, if these objects were missing or changed, the activities and subsequent learning would have turned out differently in the classroom. Therefore, to explain students' learning in the classroom, didactic transposition theory tells us that sometimes the explanations can be found at different institutional levels of the educational system, not necessarily in the classroom or in the curriculum alone.

In our framework we are using the concept of transformation instead of transposition. The reasons for this are twofold. First, transposition as a term has the semantic meaning of movement of something from one setting to another, while transformation as a term focuses on the process of change. In our view we think that it is the connotation of 'change' and

‘process’ that is most useful to study in relationship to powerful knowledge. The movement or transposition of the body of knowledge between institutions in transposition theory is more related to the explanation for this change. Second, our ambition is to encapsulate different frameworks of didactical research also relating to the classroom level, and that would be difficult by using the concept of transposition that is specifically situated within the specific framework of ATD.

The concept of didactic transposition resonates with Bernstein’s (1971) conception of ‘re-contextualization’, which refers to the selection, sequencing and pacing of contents that takes into account both the coherence of the subject discipline and the limits on what can be learned by students at different stages of their development. The concept of re-contextualization also recognizes the dichotomization between what can be regarded as powerful knowledge at the university level and what can be regarded as powerful knowledge at the school subject level and therefore we regard the idea of re-contextualisation as a useful conceptual tool for analysis of powerful knowledge in the educational system. However, the idea of re-contextualisation refers more to a conscious act of preparing for teaching at the classroom level (which will be discussed in next section), while the concept of didactic transposition relates to discourse analysis, to detect unconscious ‘taken for granted’ restraints of what is being taught at the institutional level. Pierre Clément (2006) has developed the KVP-model and showed that the transposition between institutions is dependent not only on the knowledge (K) itself, but also on values (V) and social practices (P) that in the eyes of the teachers implicitly influence the transformation processes.

School subjects and the academic disciplines have different aims. The subjects do not have the role to produce new knowledge, which could be said to be the main purpose of the academic disciplines (Gericke et al. 2014). The aim of the school subjects and the school as a whole is more differentiated, incorporating educational goals relating to for example values (equality, democracy etc.) and skills (critical thinking, action competence). These various goals of education are captured by Biesta (2009; 2015) in the conceptual triad consisting of: *qualification* (to be able to qualify for a life at and beyond school), *socialisation* (to be able to understand and act within social practices at and beyond school), and *subjectification* (to be able to understand and create meaning in relation to school practices). With reference to Biesta the transformation of powerful knowledge at an institutional level can be viewed as filtered through the triad, i.e. the content knowledge needs to be adapted by the educational goals at hand (Nordgren, 2017). Also depending on whether a literacy (socialization), or preparation for tertiary education (qualification) is the purpose of schooling, what is regarded as powerful knowledge might differ.

To summarize, the fact that the transformation process tends to come out differently depending on the setting of the institution and the goals of education, it is of interest to investigate the very nature of powerful knowledge when these variables differ.

### ***Transformation on a classroom level***

We now turn to the classroom level, the last step in the transformation process, which we would point out as the most important level. Within the German/Nordic research tradition of didactics transformation is perceived as an integrative process. This means that the representation of the teaching content in a teaching situation should not be exclusively framed as a question of how, as a methodological/pedagogical issue, as proposed by Young (2015b).

The matter of how is only a part of a bigger complex process of transformation. The answer to the how-question is dependent of the answers on the other didactical questions: what? why? For who? and when? We understand these questions as essential when discussing the process of transformation on the classroom level, and essential when discussing powerful knowledge. At the classroom level the teacher, and to some extent the students, become actors in the process of defining powerful knowledge.

Historically, in research conducted within the European research tradition of ‘didaktik’ there has been an understanding that there is a dimension in the teacher’s work, where the teacher is independent and where the teacher has the opportunity to make didactical decisions. In the research of didactics the teacher is not understood as implementing a given curriculum as in the curriculum tradition. As a consequence, to define powerful knowledge can not only be an issue of curriculum principles, but teachers and students become important parts of the enactment process. The work of the teacher then becomes defined as an interpreting activity (Westbury 2000), but this interpretation is not carried out in a vacuum. It is obviously influenced by governance and policy, but also by the traditions of teaching that are expressed in different kinds of teaching artefacts and activities. The public view of the subject, what the content should be and how the teaching ought to be organized, are also aspects of that wider context that influence the transformation process (Gericke 2009; Olin-Scheller 2006; Stolare 2017; Eliasson & Nordgren 2016; Bladh 2014).

Transformation can be characterized as a situated process that is permeating different parts of the teaching practice (Ulljens 1997; Hopmann 2007). An initial transformation is made in the planning phase, when the teacher draws up the lesson plans, selecting the teaching content and considering how it should be represented in such a way that it would be possible for the students to grasp. A second part takes place in the actual teaching situation, when teachers and students are confronted with the representations of content. In this way, the transformation can be described as process of continuous reconstruction that Ongstad (2006) has denoted as ‘omstilling’. To view transformation in this way points to one of the foundations of the German/Nordic didactic tradition; the idea of *the didactic triangle*, see Figure 1.

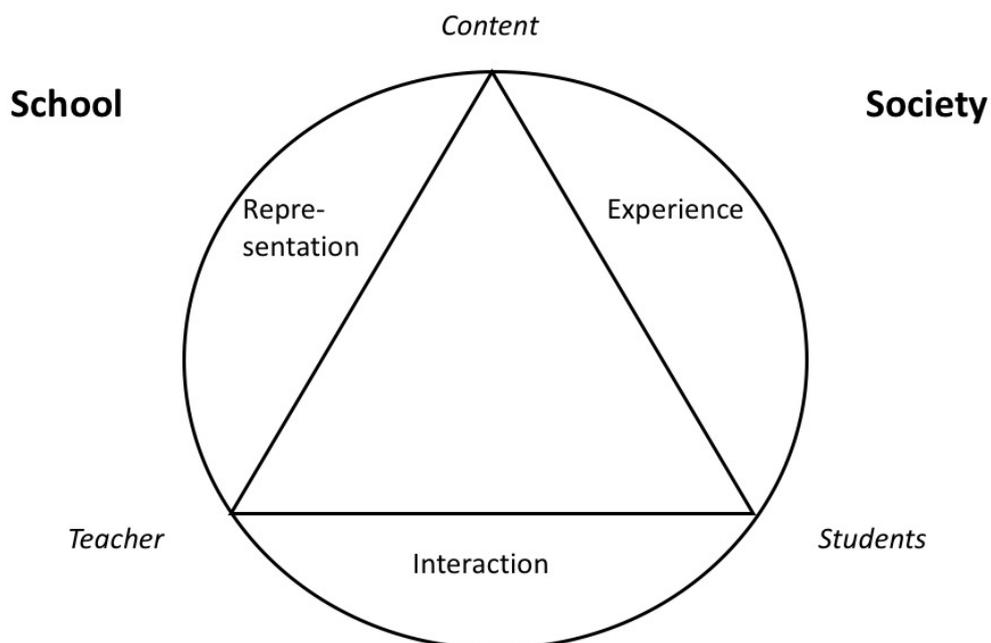

Figure 1. The didactic triangle, developed from (Klafki, 1997)

The didactic triangle captures an integrative model of the various factors that shape the processes of teaching and learning (Klafki 1997). It is integrative in the sense that it is not really considered possible to isolate a single aspect of the model. It is a relational model that stresses the interdependence of the variables. The three vertices of the triangle – the teacher, the student and the content – and especially the relationship between them are all in play and relevant to the transformation process. (Kansanen & Meri 1999). The transformation process is influenced by the students' understanding and their previous experience of the content. Here the triangle is connected to the life world of the students, and of relevance is the relationship between the teacher and the student, but also the teacher's notion of the students' relation to the content (Klafki 1997). Finally, the teacher's meta-understanding should be taken into consideration. If a teacher's work is viewed as an act of interpretation, the importance of the teacher's own understanding of the subject and to the content to be taught becomes crucial for the enactment in the classroom. But these relationships are not to be isolated from the context of the school and the society as a whole. The didactic triangle is socially and culturally embedded.

Taking the model of the didactic triangle into consideration we would claim that to be able to discern powerful knowledge at the classroom level we need to empirically investigate teachers' and students' understandings of the content knowledge and not only take our departure from the disciplinary knowledge itself. In previous research inspired by the didactic tradition, it has become clear that the didactic triangle might be used as a tool in more in-depth micro-studies focusing on the act of content negotiations between the teacher and the students. This is a process, in which both parties are important, and where the goal is to reach a (common) understanding of the content knowledge. Another conclusion is that teachers have difficulties to introduce subject perspectives related to powerful knowledge, due to teachers' own prior understanding of the content knowledge and strong selective subject traditions (Stolare 2017). This means that it is essential to identify what powerful knowledge is possible to teach based on the relationships shown in the model of the didactical triangle. One way of doing that is to use the framework of *didactical analysis* as proposed by Klafki (1995).

The framework of didactical analysis consists of five questions (Klafki 1995). These questions are based in turn on the earlier ideas proposed by Nohl and Weniger. The basic idea is that the value of any content knowledge can only be ascertained with reference to the individual learner and with a particular human and historical situation in mind, with its attendant past and anticipated future. The questions are:

1. What wider or general sense of reality do these contents exemplify and open up for the learner? What basic phenomenon or fundamental principle, what law, criterion, problem, method, technique or attitude can be grasped by dealing with this content as an 'example'?
2. What significance does the content in question or the experience, knowledge, ability or skill to be acquired through this topic already possess in the minds of the children in my class? What significance should it have from a pedagogical point of view?
3. What constitutes the topic's significance for the children's future?

4. How is the content structured? (How has the content been placed into a specifically pedagogical perspective by questions 1, 2 and 3?)
5. What are the special cases, phenomena, situations, experiments, persons, elements of aesthetic experience, and so forth, in terms of which the structure of the content in question can become interesting, stimulating, approachable, conceivable, or vivid for children of the stage of development of this class?

Through this framework, the classroom practice can be analysed and what becomes clear is that behind these questions lies a strategy addressing the issue of *significance*. What is to be taught, that we here would denote powerful knowledge, should be of significance seen from the view of the children's future (question #3). Significance points towards the importance of values, because this can only be evaluated based on the goals of education. The question to address is what knowledge has the capacity to empower students? And this can be only be answered in the light of the goals of education, be it *qualification*, *socialisation* or *subjectification* (Biesta, 2009; 2015).

In his later work Klafki discussed *Epochaltypische Schlüsselproblemen* (Key problems). In short, education should deal with the important, and sometimes controversial societal issues of today (Klafki, 1997). By doing that Klafki puts the didactical practice in clear connection to surrounding society that we discussed in a previous section. Hence, the different levels of the educational system as outlined in this article should not be viewed as independent. Instead we view them as connected and mutually interdependent through the various transformation processes as outlined. That is why it is crucial to expand the concept of powerful knowledge to also encompass the various transformation processes and their importance for teaching and learning.

With reference to Klafki's (1995) framework of *didaktik analysis*, Barrett et al. (2018) note that having reduced the knowledge-to-be-taught to digestible learning bites, this process helps the teacher to show how the reduction can be 'unlocked' to expand the range of its generalizability and induct the learner into 'unlocking' it himself or herself, a process called 'double unlocking' (Krüger, 2008). They observe how this adds an extra dimension to the Bernsteinian (2000) concept of 'recontextualisation' i.e. the curriculum is not just to be translated but rather it is also to be compressed and then de-compressed. It is this dimension that Deng (2015) thinks social realists such as Young have so far missed when developing the concept of powerful knowledge. At the same time they (ibid.) note that Bernstein shared the *didaktik* view of the unity of curriculum and pedagogy and that he acknowledged Klafki with thanks on this point in the notes to his chapter (Bernstein, 1971, p. 175). Furthermore they observe, quite rightly in our view, that this unity is a point that seems to have been lost in contemporary curriculum studies, i.e. that we would refer to as transformations.

In parallel with developments in the German/Nordic tradition, the French research tradition has developed frameworks to understand and describe the transformation processes at the classroom level. The need for integrative thinking in contrast to reductionism is also reflected in the Francophone tradition as elaborated by Sensevy (2011) who argues that the first theoretical principle of French didactics is that in order to understand a didactic activity (i.e. an activity where someone teaches and someone learns) you need to understand a system, the didactic system, which is a system of three subsystems: knowledge, the teacher and the student. The *Joint Action Theory of Didactics* (JATD) operationalizes this holistic view into a systematically organised set of concepts and analytic tools that can be used in relation to classroom observation studies. Hence, these tools were already originally developed from a research perspective rather than a curriculum perspective (Sensevy, 2011). The theory of

JATD elaborates the last step of the didactic transposition, i.e. transformation process in the classroom. In comparison to Klafki's frameworks, the tools and concepts of JATD are of more analytical nature. Within JATD the concept of the *didactic contract* is used to describe the system of *habits*, which is largely implicit, between the teacher and the students in relation to the knowledge in question. On the basis of those habits established in the *didactic situation*, each participant (the teacher or the student/s) attributes some expectations to the other(s). In order to learn, students have to deal with a *situation* involving a problem that previous knowledge does not allow them to solve. Within JATD this situation is referred to as a *milieu* (Brousseau, 1997) which describes the system of material and symbolic objects in question that corresponds to the new knowledge the students are to acquire. According to this description, the older pieces of knowledge enable the teacher and the students to act jointly whereas the new knowledge involves a kind of resistance to the student's action (Gruson et al., 2012, p. 65). Here we see a possible connection to powerful knowledge, and also JATD aims at identifying the transformed knowledge in the classroom. However, in this theory the powerful knowledge is acted upon and transformed by both the teachers and the students, which is our standpoint in this paper.

The didactic transactions between the teacher and the students are in JATD described as a game of a particular kind, a *didactic game* in which some specific pieces of knowledge are involved. The didactic game is seen as a collaborative game, a joint game, within a joint *action* (Gruson et al., 2012, p. 65). One exemplar of the application of JATD to a particular episode of classroom interaction can be found in Hudson (2015). The findings from this study highlight the ways in which the children actively engaged in the 'milieu' and the ways in which the teacher developed the 'didactic game' by extending the 'epistemic games' through the use of the open-ended topic-based approach combined with effective teacher questioning. He also highlight the ways in which the discursive elements of 'learning games' as part of these lessons proved to be very effective means through which to support the children to engage in the milieu and to develop mathematical thinking. A second exemplar is a case of teaching-learning in a non-schooling context which is based on education for toddlers with aquatic motor-awakening activities, commonly referred to as "swimming babies". This paper presents a case study of how a young girl learned how to "blow bubbles" under water (Loquet, 2011). The reason for us addressing JATD is that we believe it to be a useful tool for those interested in investigating the enactment of powerful knowledge in the classroom.

What we have tried to show from these **frameworks** of didactical research at the classroom level from the Nordic/German as well as French traditions is that it is almost impossible to make a clear dichotomization between curriculum and pedagogy because teaching and learning is mutually interdependent according to these didactical theories. It is not possible to establish powerful knowledge without considering these transformation processes. In the next section, we will make a synthesis and discuss how the concepts of transformation and powerful knowledge could relate to each other, and how we could explore this relationship.

## **Powerful knowledge and transformation – A synthesis into an integrative research framework**

We find that the concept of powerful knowledge give merits to subject didactic research, as discussed above, by pointing out the importance of the disciplinary knowledge, and how this disciplinarily knowledge needs to be defined, problematized and structured before teaching. However, from our perspective the dichotomization between curriculum and pedagogy as

well as teaching and learning is not fruitful and we see the need to expand the theory of powerful knowledge and relate it to the research traditions of didactics in general and the concept of transformation in particular. Based on this article we suggest that:

- Powerful knowledge should be considered in relation to transformation as a flexible concept that can be described and identified at the levels of society, institutions and classroom,
- as a consequence, what constitutes powerful knowledge might differ between these levels,
- these possible differences are dependent on the transformation processes occurring between the levels and
- tools for investigating the transformation processes leading to a specific set of powerful knowledge can be found in the European research traditions of didactics.

Accordingly, powerful knowledge cannot be defined solely on the discipline, but needs to be adopted by considering the didactization<sup>2</sup> (Ongstad 2006) of the conceptual knowledge through the transformation process. If there are obstacles in the transformation process (for example students might lack the necessary pre-knowledge to understand the concept, or the students' might have negative attitudes depending on the social context) it would not be meaningful to teach it. Therefore, we need to consider transformation while identifying powerful knowledge.

Further, not all school subjects are linked to a discipline(s) in the same way. Some school subjects are connected to a single discipline (e.g. History, Mathematics) but other school subject have connections to several different disciplines (e.g. Science, Mother tongue, Civics). Those school subjects might be described as interdisciplinary by their very nature. Keeping these facts in mind we think it is necessary to investigate and compare transformation processes and powerful knowledge over many school subjects and disciplines. By focusing on powerful knowledge and the corresponding transformation processes through a comparative approach, it should be possible to illuminate the didactical commonalities and differences between different subjects and how they influence teaching and learning. In contemporary didactical research, the focus is shifting more towards what we in this paper denotes as “research on subject specific education” or what in a European tradition is denoted “ämnesdidaktik” (Swedish), “fachdidaktik” (German) or “didactiques des disciplines” (French). The starting point in subject specific education is that the different knowledge traditions and epistemologies of different subjects are diverse, and these premises are decisive in teaching and learning, and will inevitably influence both the way content is selected (the what and why questions) and the way it is taught (the how question). In that sense, it conforms with the ideas of transformation and powerful knowledge as formulated in this article. Thus, drawing on both a subject-specific and a cross disciplinary perspective, we argue for a research framework to investigate processes of how powerful knowledge is manifested in teaching and perceived by students and teachers in different subjects and topics.

The ambition in this article has been to point to the importance of linking the traditions of didactics, here especially the German/Nordic and the French, to the curriculum perspective of powerful knowledge. This has been done by applying an inclusive definition of the concept of transformation. The idea is that through the holistic integrative didactic approach emphasise is placed on the complexity of the transformation of powerful knowledge in relation to the school subjects. But also it is suggested that the concepts present in the didactic traditions, some of which discussed here, as the didactic triangle, the didactic questions, transposition,

---

<sup>2</sup> The process of which a school subject is adopted for teaching due to societal and contextual influences.

(epistemic-, didactic-, learning-) games could work as frameworks to better grasp and unfold the process of transformation. The next step will be to establish a more elaborated framework, and this can be done only through empirical studies, preferably of comparative nature as argued above. In doing so we would, based on this paper, suggest that research should follow these three overarching research questions:

1. How can the nature of powerful knowledge in different school subjects be characterized?
2. How can the transformation processes related to powerful knowledge be described?
3. What are the barriers against and the conditions for transformation of powerful knowledge in different subjects?

With these proposals we believe that there are good possibilities to develop the theoretical, as well as empirical, underpinnings of the concept of powerful knowledge and at the same time start the merging process of curriculum research with didactical research by combining the most advantageous aspects from both traditions.
